Abstract

We investigate a widely popular least-recently-used (LRU) cache replacement algorithm with semi-Markov modulated requests. Semi-Markov processes provide the flexibility for modeling strong statistical correlation, including the widely reported long-range dependence in the World Wide Web page request patterns. When the frequency of requesting a page n is equal to the generalized Zipf's law c/n^α , $\alpha > 1$, our main result shows that the cache fault probability is asymptotically, for large cache sizes, the same as in the corresponding LRU system with i.i.d. requests. The result is asymptotically explicit and appears to be the first computationally tractable average-case analysis of LRU caching with statistically dependent request sequences. The surprising insensitivity of LRU caching performance demonstrates its robustness to changes in document popularity. Furthermore, we show that the derived asymptotic result and simulation experiments are in excellent agreement, even for relatively small cache sizes.

1. Introduction

The basic idea of caching is to maintain high-speed access to a subset of k items out of a larger collection of N documents that cannot be accessed quickly. Originally, caching was used in computer systems to speed up the data transfer between the central processor unit and slow local memory. The renewed interest in caching stems from its application to increasing the speed of accessing Internet Web documents.

One of the fundamental issues of caching is the problem of selecting and possibly dynamically updating the k items that need to be stored in the fast memory (cache). The optimal solution to this problem is often very difficult to find and, therefore, a number of heuristic, usually dynamic, cache updating algorithms have been proposed. Among the most popular algorithms are those based on the least-recently-used (LRU) cache replacement rule. The wide popularity of this rule is primarily due to its high performance and ease of implementation. LRU algorithm tends to both keep more frequent items in the cache as well as quickly adapt to potential changes in document popularity, resulting in efficient performance.

In order to further the insight into designing network caching algorithms, it is important to gain a thorough understanding of the baseline LRU cache replacement policy. Basic references on the performance analysis of caching algorithms can be found in Section 6 of Knuth [19]. In the analysis of LRU caching scheme there have been two approaches: combinatorial and probabilistic studies. For the combinatorial (amortized, competitive) analysis the reader is referred to Bentley and McGeoch [3] and Sleator and Tarjan [25]; recent results and references for this approach can be found in Borodin et al. [5] and Irani et al. [15]. In this paper we focus on the average-case or probabilistic analysis.

Early work on the probabilistic analysis of LRU caching, and the related move-to-front (MTF) searching, algorithm with i.i.d. requests dates back to McCabe [20]. This work has been followed by investigations of Burville and Kingman [6], Rivest [23], Bitner [4], Phatarfod [22], Fill [12], Flajolet et al. [14] and others; a more extensive list of references and brief historical overview can be found in [16].

Recently, for the independent reference model, in [16] a new analytically tractable asymptotic approximation technique of the LRU fault probability was developed. However, an equivalent understanding of LRU performance with statistically dependent request sequences is still lacking. Several papers, including Rodrigues [24], Dobrow and Fill [10] and Coffman and Jelenković [8], develop representation results for the LRU cache fault probability, but these results appear to be computationally intractable, as pointed out in [8]. Despite the lack of analytical tractability, numerous empirical studies, e.g. see [1], emphasize the importance of understanding the caching behavior in the presence of strong statistical correlation, including the long-range dependence.

In order to alleviate the preceding problem, this paper provides the first explicit asymptotic characterization of the LRU cache fault probability in the case of statistically dependent requests. Our doubly stochastic Poisson reference model, capable of capturing a broad range of statistical correlation, is described in the following section. Using this model and the Poisson decomposition/superposition properties, similarly as in Fill [11], in Section 3 we develop a representation theorem for the stationary search cost distribution. This representation theorem provides a starting point for our large deviation analysis that, for the case of generalized Zipf's law requests, yields the main results stated in Theorems 2 and 3.

Informally, our main results show that the LRU fault probability is asymptotically invariant to the underlying dependency structure of the modulating process, i.e., for large cache sizes, the LRU fault probability behaves exactly the same as in the case of independent request sequences [16]. This may appear surprising given the impact that the statistical correlation has on the asymptotic performance of queuing models, e.g. see [18]. Furthermore, in Section 5 extensive numerical experiments show an excellent agreement between our analytical results and simulations. The paper is concluded in Section 6 with a brief discussion on the impact of our findings on designing network caching systems.

2. Model description

Consider N items, out of which k are kept in a fast memory (cache) and the remaining $N - k$ are stored in a slow memory. Each time a request for an item is made, the cache is searched first. If the item is not found there, it is brought in from the slow memory and replaced with the least recently accessed item from the cache. Such a replacement policy is commonly referred to as LRU, as previously stated in the introduction. The performance quantity of interest for this algorithm is the LRU fault probability, i.e. the probability that the requested item is not in the cache. Our goal in this paper is to asymptotically characterize this probability.

The fault probability of the LRU caching is equivalent to the tail of the searching cost distribution for the MTF searching algorithm. In order to justify this claim, we note that k elements in the cache, under the LRU rule, are arranged in increasing order of their last access times. Each time there is a request for an item that is not in the cache, the item is brought to the first position of the cache and the last element of the cache is moved to the slow memory. We argue that the fault probability stays the same if the remaining $N - k$ items in the slow memory are arranged in any specific order. In particular, they can be arranged in the increasing order of their last access times. The obtained algorithm is then the same as the MTF searching algorithm. Additional arguments that justify the connection between the MTF search cost distribution and LRU cache fault probability can be found in [14,11], and [16]. Hence, we proceed with a description of the MTF algorithm.

More formally, consider a finite set of items $L = \{1, \dots, N\}$, and a sequence of requests that arrive at points $\{\tau_n, -\infty < n < \infty\}$ that represent a Poisson process of unit rate. At each point τ_n , we use R_n to denote the document that has been requested, i.e., the event $\{R_n = i\}$ represents a request for document i ; we assume that the sequence $\{R_n\}$ is independent of the arrival Poisson points $\{\tau_n\}$. The dynamics of the MTF algorithm are defined as follows. Suppose that the system starts at the moment τ_0 of 0th request with an initial permutation Π_0 of the list. Then, at every time instant $\tau_n, n \geq 0$, that an item, say i , is requested, its position in the list is first determined; if i is in the k th position we say that the search cost C_n^N for this item is equal to k . Now, the list is updated by moving item i to the first position of the list and items in positions $1, \dots, k - 1$, are moved one position down. Note that, according to the discussion in the preceding paragraph, $\mathbb{P}[C_n^N > k]$ represents the stationary fault probability for a cache of size k .

In the remaining part of this section, we describe the dependency structure of the request sequence $\{R_n\}$. Let $\{T_n, -\infty < n < \infty\}$, $T_0 \leq 0 < T_1$, be a point process with almost

surely (a.s.) strictly increasing points $(T_{n+1} > T_n)$ and $\{J_{T_n}, -\infty < n < \infty\}$ a finite-state-space process taking values in $\{1, \dots, M\}$. Then we construct a piecewise constant right-continuous *modulating process* J as

$$J_t = J_{T_n}, \quad \text{if } T_n \leq t < T_{n+1}.$$

We assume that J is stationary and ergodic with stationary distribution $\pi_k = \mathbb{P}[J_t = k]$ and independent of Poisson points $\{\tau_n\}$. Next, for any $k, m \leq M$, we assume the asymptotic independence

$$\mathbb{P}[J_t = k | J_0 = m] \rightarrow \pi_k \quad \text{as } t \rightarrow \infty. \tag{1}$$

To avoid trivialities, we assume that $\min_k \pi_k > 0$.

For each $1 \leq k \leq M$, let $q_i^{(k)}, 1 \leq i \leq N$, be a probability mass function; $q_i^{(k)}$ is used to denote the probability of requesting item i when the underlying process J is in state k . Next, the dynamics of R_n are uniquely determined by the modulating process J according to the following equation:

$$\mathbb{P}[R_l = i_l, 1 \leq l \leq n | J_t, t \leq \tau_n] = \prod_{l=1}^n q_{i_l}^{(J_{\tau_l})}, \quad n \geq 1, \tag{2}$$

i.e., the sequence of requests R_n is conditionally independent given the modulating process J . Therefore, the constructed request process $\{R_n\}$ is stationary and ergodic as well. We will use

$$q_i = \mathbb{P}[R = i] = \sum_{k=1}^M \pi_k q_i^{(k)}$$

to express the marginal request distribution, with the assumption that $q_i > 0$ for all $1 \leq i \leq N$. The preceding processes are constructed on a probability space $(\Omega, \mathcal{F}, \mathbb{P})$.

3. Preliminary results

In this section we first prove, in Lemma 1, that the search cost random variable C_n^N converges to stationarity when the request process $\{R_n\}$ is stationary and ergodic; note that, only in this lemma, we suppose these more general conditions on $\{R_n\}$ than those assumed in the previous section. Then, in the following subsection we give properties of the stationary search cost distribution in Theorem 1 and Proposition 1. The remaining part of the section contains the results on MTF searching with i.i.d. requests that will be used in proving our main theorems.

Lemma 1. *If the request process $\{R_n\}$ is stationary and ergodic, then for any initial permutation Π_0 of the list, the search cost C_n^N converges in distribution to C^N as $n \rightarrow \infty$, where*

$$C^N \triangleq \sum_{i=1}^N \sum_{m=1}^{\infty} (1 + S_i(m-1)) \mathbb{1}[R_{-m} = i, \mathcal{R}_i(m-1), R_0 = i],$$

$S_i(m)$ is the number of distinct items, different from i , among R_{-m}, \dots, R_{-1} and event $\mathcal{R}_i(m) \triangleq \{R_{-j} \neq i, 1 \leq j \leq m\}$, $m \geq 1$; $S_i(0) \equiv 0$, $\mathcal{R}_i(0) \equiv \Omega$.

Proof. For simplicity let $C_n \equiv C_n^N$. Note that, due to the stationarity of the request process $\{R_n\}$, C_n is equal in distribution to the search cost $C_0^{(n)}$ at the moment of 0th request τ_0 , given that the MTF process started at time τ_{-n} with initial permutation Π_0 . Now, each of the summands of the following identity

$$C_0^{(n)} = \sum_{i=1}^N C_0^{(n)} 1[R_0 = i] \tag{3}$$

can be represented as

$$C_0^{(n)} 1[R_0 = i] = \sum_{m=1}^n (1 + S_i(m-1)) 1[R_{-m} = i, \mathcal{R}_i(m-1), R_0 = i] + C_0^{(n)} 1[\mathcal{R}_i(n), R_0 = i], \tag{4}$$

since $C_0^{(n)} = 1 + S_i(m-1)$ on event $\{R_{-m} = i, \mathcal{R}_i(m-1), R_0 = i\}$. The second term in the preceding equality is bounded by $N 1[\mathcal{R}_i(n)]$, which, by ergodicity, satisfies a.s.

$$\lim_{n \rightarrow \infty} N 1[\mathcal{R}_i(n)] = 0.$$

Thus, the last limit, monotonicity of the sum in (4) and identity (3) imply that $C_0^{(n)}$ converges a.s. to C^N as $n \rightarrow \infty$. Therefore, C_n^N converges in distribution to C^N as $n \rightarrow \infty$. \square

3.1. Representation theorem

At this point, we will derive a representation theorem for the stationary search cost C^N , as defined in Lemma 1. Note that C^N is uniquely defined by the request process $\{R_n, n \leq 0\}$ and, therefore, it implicitly depends on $\{J_{\tau_0+t}, t \leq 0\}$. However, since τ_0 is independent from $\{J_t\}$, the process $\{J_{\tau_0+t}, t \leq 0\}$ is equal in distribution to $\{J_t, t \leq 0\}$. Thus, without loss of generality we can set $\tau_0 = 0$. Next, let τ_{-1}^i be the last moment of time $t < 0$ that item i was requested. Then, an equivalent continuous time representation of C^N is

$$C^N = \sum_{i=1}^N (1 + S_i(-\tau_{-1}^i; J)) 1[R_0 = i],$$

where, similarly as in Lemma 1, $S_i(t; J)$ represents the number of distinct items, different from i , that are requested in interval $[-t, 0)$. Now, using double conditioning and the last identity, we arrive at

$$\mathbb{P}[C^N > x] = \mathbb{E} \int_0^\infty \sum_{i=1}^N \mathbb{P}_{\sigma_t} \left[S_i(t; J) > x - 1, R_0 = i, \tau_{-1}^i \in (-t, -t + dt) \right],$$

where σ_t is the σ -algebra $\sigma(J_u, -t \leq u \leq 0)$ and $\mathbb{P}_{\sigma_t}[\cdot] = \mathbb{P}[\cdot | \sigma_t]$. Using the fact that the request process R_n , by (2), is conditionally independent given the modulating process J_t and that the variables $S_i(t; J)$ and τ_{-1}^i are uniquely determined by the values of $\{R_n, n \leq -1\}$ and the Poisson arrivals for $t < 0$, we conclude that R_0 is conditionally independent from $S_i(t; J)$ and τ_{-1}^i , given σ_t , and thus

$$\mathbb{P}[C^N > x] = \mathbb{E} \int_0^\infty \sum_{i=1}^N q_i^{(J_0)} \mathbb{P}_{\sigma_t} \left[S_i(t; J) > x - 1, \tau_{-1}^i \in (-t, -t + dt) \right]. \quad (5)$$

Next, we intend to show that variables $S_i(t; J)$ and τ_{-1}^i are conditionally independent given σ_t . To this end, we exploit the Poisson superposition/decomposition properties of the arrival process. Let $N_j(u; J)$ be the number of requests for item j in $[-u, 0)$, $0 < u \leq t$ and $B_j(t; J) = 1[N_j(t; J) > 0]$. Then, $S_i(t; J)$ can be represented as

$$S_i(t; J) = \sum_{j \neq i, 1 \leq j \leq N} B_j(t; J). \quad (6)$$

Now, we show that, for different j , processes $\{N_j(u; J), 0 < u \leq t\}$ are mutually independent Poisson processes given σ_t . In this regard, for any $t \geq u > 0$, let V_n be an interval in $[-u, 0)$ on which the modulating process stays constant, i.e.

$$V_n = [T_{n+1} \wedge 0] - [T_n \vee (-u)],$$

where $a \wedge b \equiv \min(a, b)$ and $a \vee b \equiv \max(a, b)$. Since, by (2), the request process is conditionally independent given σ_t , and independent from the Poisson arrival points, the Poisson decomposition theorem (see Section 4.5 of [7]) implies that the number of requests for item j in an interval V_n , given σ_t , is a Poisson variable with expected value $q_j^{(J_{T_n \vee (-u)})} V_n$. Furthermore, the Poisson variables for different j and different intervals V_n are independent given σ_t . Thus, given σ_t , aggregating the independent Poisson requests for item j over all intervals $V_n \subset [-u, 0)$, by Poisson superposition theorem (see Section 4.4 of [7]) shows that $N_j(u; J)$ are mutually independent Poisson variables for different j . Furthermore, by repeating the preceding arguments over an arbitrary set of disjoint intervals $[-u_m, -u_{m-1}), \dots, [-u_1, 0)$, $0 < u_1 \leq \dots \leq u_{m-1} \leq u_m \leq t$, it easily follows that, for different j , $\{N_j(u; J), 0 < u \leq t\}$ are mutually independent Poisson processes given σ_t . In particular, for any fixed t , the Bernoulli variables $B_j(t; J)$ are conditionally independent given σ_t with

$$\mathbb{P}_{\sigma_t}[B_j(t; J) = 1] = 1 - e^{-\hat{q}_j t}, \quad (7)$$

where $\hat{q}_j \equiv \hat{q}_j(t)$ and $\hat{\pi}_k \equiv \hat{\pi}_k(t)$ are defined as

$$\hat{q}_j = \sum_{k=1}^M q_j^{(k)} \hat{\pi}_k \quad \text{and} \quad \hat{\pi}_k = \frac{1}{t} \int_{-t}^0 1[J_u = k] du. \quad (8)$$

Therefore, since $\{-\tau_{-1}^i > t\} = \{N_i(t; J) = 0\}$, the conditional independence of variables $N_j(t; J)$ and Eq. (6) show that $S_i(t; J)$ and τ_{-1}^i are conditionally independent given σ_t .

Using this fact and

$$\begin{aligned} & \mathbb{P}_{\sigma_t}[\tau_{-1}^i \in (-t, -t + dt)] \\ &= \mathbb{P}_{\sigma_t}[N_i(t - dt; J) = 0, N_i(t; J) - N_i(t - dt; J) = 1] \\ &= e^{-\hat{q}_i t} q_i^{(J-t)} dt \end{aligned}$$

in (5) we derive the following representation theorem.

Theorem 1. *The stationary distribution of the searching cost C^N satisfies*

$$\mathbb{P}[C^N > x] = \mathbb{E} \int_0^\infty \sum_{i=1}^N q_i^{(J_0)} q_i^{(J-t)} e^{-\hat{q}_i t} \mathbb{P}_{\sigma_t}[S_i(t; J) > x - 1] dt, \tag{9}$$

with $S_i(t; J)$, $B_j(t; J)$, and \hat{q}_j satisfying Eqs. (6)–(8), respectively.

Remark 1. Throughout this paper we will use the property that the variables $S_j(t; J)$, $B_j(t; J)$, $j \geq 1$, are monotonically increasing in t and $B_j(t; J)$, $j \geq 1$, are conditionally independent given σ_t . This conditional independence, as is apparent from the derivation, arises from the Poisson arrival structure. In general, when the request times are not Poisson, e.g. discrete time arrivals, these variables may not be conditionally independent. However, our approach can be extended by embedding the request sequence into a Poisson process; for i.i.d. requests, the Poisson embedding technique was first introduced in [13].

Remark 2. It is clear that the preceding analysis does not rely on the fact that the requests arrive at a constant rate. Thus, our results can be generalized to the case where the arrival rate depends on the state of the modulating process J , i.e., the rate can be set to λ_k when $J_t = k$. We do not consider this extension, since it further complicates the notation without providing any significant new insight.

In the proposition that follows, we investigate the limiting search cost distribution when the number of items $N \rightarrow \infty$. Now, assume that the probability mass functions $q_i^{(k)}$, $1 \leq k \leq M$ are defined for all $i \geq 1$. Using these probabilities, for a given modulating process J and each $1 \leq N \leq \infty$ we define a sequence of request processes $\{R_n^N\}$, whose conditional request probabilities are equal to

$$q_{i,N}^{(k)} = \frac{q_i^{(k)}}{\sum_{i=1}^N q_i^{(k)}}, \quad 1 \leq i \leq N;$$

then, for each finite N , let C^N be the corresponding stationary search cost. In the case of the limiting request process $R_n = R_n^\infty$, similarly as in (6), introduce $S_i(t; J) = \sum_{j \neq i} B_j(t; J)$ to be equal to the number of different items, not equal to i , that are requested in $[-t, 0)$; $B_j(t; J)$ is the Bernoulli variable representing the event that item j was requested at least once in $[-t, 0)$. Now, we prove the limiting representation result that provides a starting point for our large deviation analysis in Section 4.

Proposition 1. *The constructed sequence of stationary search costs C^N converges in distribution to C as $N \rightarrow \infty$, where the distribution of C is given by*

$$\mathbb{P}[C > x] = \mathbb{E} \int_0^\infty \sum_{i=1}^\infty q_i^{(J_0)} q_i^{(J-t)} e^{-\hat{q}_i t} \mathbb{P}_{\sigma_t}[S_i(t; J) > x - 1] dt. \quad (10)$$

Remark 3. For the i.i.d. case, this result was proved in Proposition 4.4 of [12].

Proof. In order to prove the convergence in distribution, it is enough to show the pointwise convergence of distribution functions, i.e. for any $x \geq 0$, $\mathbb{P}[C^N > x] \rightarrow \mathbb{P}[C > x]$ as $N \rightarrow \infty$. This is easily achieved using the Dominated Convergence Theorem. For details see the Appendix. \square

3.2. Results for i.i.d. requests

In this section we state several results that consider LRU caching scheme with independent requests that will be used in proving our main results. The MTF model with i.i.d. requests follows from our general problem formulation when the modulating process is assumed to be a constant, i.e. $J_t \equiv \text{constant}$. In this case the Bernoulli variables $\{B_j(t), j \geq 1\}$ that indicate that an item j was requested in $[-t, 0)$ are independent with success probabilities $\mathbb{P}[B_i(t) = 1] = 1 - e^{-q_i t}$. Then, using the notation $S_i(t) = \sum_{j \neq i} B_j(t)$, it is easy to see that the distribution of the limiting stationary search cost C from Proposition 1 reduces to

$$\mathbb{P}[C > x] = \int_0^\infty \sum_{i=1}^\infty q_i^2 e^{-q_i t} \mathbb{P}[S_i(t) > x - 1] dt. \quad (11)$$

The following two results, originally proved in Lemmas 1 and 2 of [16], are restated here for convenience. In this paper we are using the following standard notation. For any two real functions $a(t)$ and $b(t)$ and fixed $t_0 \in \mathbb{R} \cup \{\infty\}$ we will use $a(t) \sim b(t)$ as $t \rightarrow t_0$ to denote $\lim_{t \rightarrow t_0} [a(t)/b(t)] = 1$. Similarly, we say that $a(t) \gtrsim b(t)$ as $t \rightarrow t_0$ if $\liminf_{t \rightarrow t_0} a(t)/b(t) \geq 1$; $a(t) \lesssim b(t)$ has a complementary definition.

Lemma 2. *Assume that $q_i \sim c/i^\alpha$ as $i \rightarrow \infty$, with $\alpha > 1$ and $c > 0$. Then, as $t \rightarrow \infty$,*

$$\sum_{i=1}^\infty q_i^2 e^{-q_i t} \sim \frac{c^{\frac{1}{\alpha}}}{\alpha} \Gamma\left(2 - \frac{1}{\alpha}\right) t^{-2 + \frac{1}{\alpha}},$$

where Γ is the Gamma function.

Lemma 3. *Let $S(t) = \sum_{i=1}^\infty B_i(t)$ and assume $q_i \sim c/i^\alpha$ as $i \rightarrow \infty$, with $\alpha > 1$ and $c > 0$. Then, as $t \rightarrow \infty$,*

$$m(t) \triangleq \mathbb{E}S(t) \sim \Gamma\left(1 - \frac{1}{\alpha}\right) c^{\frac{1}{\alpha}} t^{\frac{1}{\alpha}}.$$

The next straightforward lemma will be repeatedly used in the paper.

Lemma 4. Let $\{B_i, i \geq 1\}$ be a sequence of independent Bernoulli random variables, $S = \sum_{i=1}^{\infty} B_i$ and $m = \mathbb{E}[S]$. Then for any $\varepsilon > 0$, there exists $\theta_\varepsilon > 0$, such that

$$\mathbb{P}[|S - m| > m\varepsilon] \leq 2e^{-\theta_\varepsilon m}.$$

The proof is given in the Appendix. \square

Now, we provide a general bound on the search cost distribution for the case when the request probabilities are reciprocal-polynomially bounded. In the following two lemmas, we also allow for some of the q_i s to be equal to zero. In addition, since C takes values in nonnegative integers, we assume in the remainder of the paper, without loss of generality, that x is integer valued as well.

Throughout the paper H denotes a sufficiently large positive constant, while h denotes a sufficiently small positive constant. The values of H and h are generally different in different places. For example, $H/2 = H$, $H^2 = H$, $H + 1 = H$, etc.

Lemma 5. If $0 \leq q_i \leq H/i^\alpha$ for some fixed $\alpha > 1$, then for any $x \geq 1$,

$$\mathbb{P}[C > x] \leq \frac{H}{x^{\alpha-1}}.$$

Proof. If there are finitely many q_i s that are positive, then we can always find a large enough cache size such that the fault probability is equal to zero and the bound trivially holds. Hence, without loss of generality we can assume that $q_i > 0$ for infinitely many $i \geq 1$. Therefore, $m(t) = \sum_{i=1}^{\infty} \mathbb{B}_i(t) \nearrow \infty$ monotonically as $t \nearrow \infty$, implying that the inverse $m^{-1}(t)$ exists for any $t \geq 0$. Next, define $x_\varepsilon = (1 - \varepsilon)(x - 1)$, for arbitrarily chosen $0 < \varepsilon < 1$. Now, using $S_i(t) \leq S(t)$ in (11), we derive

$$\begin{aligned} \mathbb{P}[C > x] &\leq \int_0^{m^{-1}(x_\varepsilon)} \sum_{i=1}^{\infty} q_i^2 e^{-q_i t} \mathbb{P}[S(t) > x - 1] dt \\ &\quad + \int_{m^{-1}(x_\varepsilon)}^{\infty} \sum_{i=1}^{\infty} q_i^2 e^{-q_i t} dt \\ &\triangleq I_1(x) + I_2(x). \end{aligned}$$

Then, since $S(t)$ is a non-decreasing function in t ,

$$\begin{aligned} I_1(x) &\leq \mathbb{P}[S(m^{-1}(x_\varepsilon)) > x - 1] \int_0^{m^{-1}(x_\varepsilon)} \sum_{i=1}^{\infty} q_i^2 e^{-q_i t} dt \\ &= \mathbb{P}[S(m^{-1}(x_\varepsilon)) > x - 1] \sum_{i=1}^{\infty} q_i (1 - e^{-q_i m^{-1}(x_\varepsilon)}) \\ &\leq \mathbb{P}[S(m^{-1}(x_\varepsilon)) > x - 1], \end{aligned}$$

which, by $m(m^{-1}(x_\varepsilon)) = (1 - \varepsilon)(x - 1)$, Lemma 4, and setting $\varepsilon = \varepsilon/(1 - \varepsilon)$, implies

$$I_1(x) \leq 2e^{-\theta_\varepsilon x} = o\left(\frac{1}{x^{\alpha-1}}\right) \quad \text{as } x \rightarrow \infty. \tag{12}$$

Next,

$$\begin{aligned} I_2(x) &= \int_{m^{-1}(x_\varepsilon)}^{\infty} \sum_{i=1}^{\infty} q_i^2 e^{-q_i t} dt \\ &= \sum_{i=1}^{\infty} q_i e^{-q_i m^{-1}(x_\varepsilon)} \\ &\leq \frac{1}{m^{-1}(x_\varepsilon)} \sum_{i=1}^x q_i m^{-1}(x_\varepsilon) e^{-q_i m^{-1}(x_\varepsilon)} + \sum_{i=x+1}^{\infty} q_i. \end{aligned} \quad (13)$$

Since $\sup_{y \geq 0} (y e^{-y}) = e^{-1}$ implies $q_i m^{-1}(x_\varepsilon) e^{-q_i m^{-1}(x_\varepsilon)} \leq e^{-1}$ for all i and $\sum_{i=x+1}^{\infty} q_i \leq \int_x^{\infty} (H/u^\alpha) du$, the preceding inequality renders

$$I_2(x) \leq \frac{x e^{-1}}{m^{-1}(x_\varepsilon)} + \frac{H}{(\alpha - 1)x^{\alpha-1}}. \quad (14)$$

Next, from $q_i \leq H/i^\alpha$ follows $m(t) = \sum_{i=1}^{\infty} (1 - e^{-q_i t}) \leq \sum_{i=1}^{\infty} (1 - e^{-Ht/i^\alpha})$; and, using Lemma 3, we derive $m(t) \leq Ht^{\frac{1}{\alpha}}$, implying $m^{-1}(x_\varepsilon) \geq hx^\alpha$. Therefore

$$I_2(x) \leq \frac{H}{x^{\alpha-1}},$$

which, in conjunction with (12), proves the result. \square

Lemma 6. *If $0 \leq q_i \leq H/i^\alpha$, $\alpha > 1$, then*

$$\sum_{i=1}^{\infty} q_i e^{-q_i t} \leq Ht^{-1+\frac{1}{\alpha}}.$$

Proof. Similarly as in the proof of Lemma 5, the claim follows easily from $\sup_{y \geq 0} (y e^{-y}) = e^{-1}$, the assumption $q_i \leq H/i^\alpha$, and

$$\sum_{i=1}^{\infty} q_i e^{-q_i t} \leq \frac{1}{t} \sum_{i=1}^{\lfloor t^{\frac{1}{\alpha}} \rfloor} q_i t e^{-q_i t} + \sum_{i=\lfloor t^{\frac{1}{\alpha}} \rfloor}^{\infty} q_i,$$

where $\lfloor y \rfloor$ is the integer part of y ; we omit the details. \square

4. Main results

In this section we derive our main results in Theorems 2 and 3. These results fully generalize Theorem 3 of [16] that was proved for the independent reference model. Furthermore, our method of proof, which uses probabilistic and sample path arguments, provides an alternative approach to the Tauberian technique used in [16].

4.1. Lower bound

In preparation for our main results, we prove the following lower bound that holds for the entire class of stationary and ergodic modulating request processes, as defined in Section 2.

Proposition 2. Assume that $q_i \sim c/i^\alpha$ as $i \rightarrow \infty$ and $\alpha > 1$. Define

$$K(\alpha) \triangleq \left(1 - \frac{1}{\alpha}\right) \left[\Gamma\left(1 - \frac{1}{\alpha}\right)\right]^\alpha, \tag{15}$$

where Γ is the Gamma function. Then, as $x \rightarrow \infty$

$$\mathbb{P}[C > x] \gtrsim K(\alpha) \mathbb{P}[R > x].$$

Proof. For any $1 > \varepsilon > 0$, let $\{B_i^{-\varepsilon}(t), i \geq 1\}$ be a sequence of independent Bernoulli random variables with $\mathbb{P}[B_i^{-\varepsilon}(t) = 1] = 1 - e^{-q_i(1-\varepsilon)t}$, $S_{-\varepsilon}(t) \triangleq \sum_{i=1}^\infty B_i^{-\varepsilon}(t)$ and $m_{-\varepsilon}(t) \triangleq \mathbb{E}S_{-\varepsilon}(t) = \sum_{i=1}^\infty (1 - e^{-(1-\varepsilon)q_i t})$. Note that, using the independent reference model interpretation from the beginning of Section 3.2, $S_{-\varepsilon}(t)$ represents the number of distinct items requested in interval $[-t(1 - \varepsilon), 0)$. Therefore, we can assume that $S_{-\varepsilon}(t)$ is constructed, on a possibly extended probability space, monotonically non-decreasing in t .

We also define

$$v(t) \triangleq \max_{1 \leq k \leq M} |\hat{\pi}_k - \pi_k|, \tag{16}$$

which for all $\omega \in \{v(t) \leq \varepsilon\}$ and $1 \leq k \leq M$ implies

$$\pi_k(1 - \varepsilon) \leq \hat{\pi}_k \equiv \hat{\pi}_k(t) \leq \pi_k(1 + \varepsilon),$$

and therefore

$$q_i(1 - \varepsilon) \leq \hat{q}_i \equiv \hat{q}_i(t) \leq q_i(1 + \varepsilon), \tag{17}$$

for all $i \geq 1$. This and (7) further imply that for every $\omega \in \{v(t) \leq \varepsilon\}$

$$\mathbb{P}_{\sigma_t}[B_i(t; J) = 1] = 1 - e^{-\hat{q}_i t} \geq 1 - e^{-(1-\varepsilon)q_i t} = \mathbb{P}[B_i^{-\varepsilon}(t) = 1].$$

Therefore, for every $\omega \in \{v(t) \leq \varepsilon\}$, (by stochastic dominance, e.g. see Exercise 4.2.2, p. 277 of [2]) the total number of distinct items $S(t; J) \equiv S_i(t; J) + B_i(t; J)$ requested in $[-t, 0)$ satisfies

$$\mathbb{P}_{\sigma_t}[S(t; J) > x] \geq \mathbb{P}[S_{-\varepsilon}(t) > x]. \tag{18}$$

Then, representation expression (10) and equations (17)–(18) render

$$\begin{aligned} \mathbb{P}[C > x] &\geq \mathbb{E} \int_0^\infty \sum_{i=1}^\infty q_i^{(J_0)} q_i^{(J-t)} e^{-\hat{q}_i t} \mathbb{P}_{\sigma_t}[S(t; J) > x] dt \\ &\geq \mathbb{E} \int_0^\infty \sum_{i=1}^\infty q_i^{(J_0)} q_i^{(J-t)} e^{-q_i(1+\varepsilon)t} \mathbb{P}[S_{-\varepsilon}(t) > x] 1[v(t) \leq \varepsilon] dt. \end{aligned}$$

Now, using the last expression and monotonicity of $S_{-\varepsilon}(t)$ we derive for any $g_\varepsilon > 0$

$$\begin{aligned} \mathbb{P}[C > x] &\geq \mathbb{P}[S_{-\varepsilon}(g_\varepsilon x^\alpha) > x] \\ &\quad \times \int_{g_\varepsilon x^\alpha}^{\infty} \sum_{i=1}^{\infty} e^{-q_i(1+\varepsilon)t} \mathbb{E} \left[q_i^{(J_0)} q_i^{(J-t)} 1[v(t) \leq \varepsilon] \right] dt. \end{aligned} \quad (19)$$

The ergodicity of J , asymptotic independence from (1) and finiteness of its state space implies that uniformly in k, l and all t large enough ($t \geq t_\varepsilon$)

$$\mathbb{P}[v(t) \leq \varepsilon, J_0 = k, J_t = l] \geq (1 - \varepsilon) \pi_k \pi_l,$$

which yields for all $i \geq 1$ and t large,

$$\mathbb{E} \left[q_i^{(J_0)} q_i^{(J-t)} 1[v(t) \leq \varepsilon] \right] \geq (1 - \varepsilon) q_i^2. \quad (20)$$

Next, if we choose

$$g_\varepsilon = \frac{(1 + 2\varepsilon)^\alpha}{c(1 - \varepsilon) \left[\Gamma\left(1 - \frac{1}{\alpha}\right) \right]^\alpha},$$

then, it is easy to check that, by Lemma 3, $m_{-\varepsilon}(g_\varepsilon x^\alpha) \sim (1 + 2\varepsilon)x$ as $x \rightarrow \infty$, from which, for all x large ($x \geq x_\varepsilon$), it follows that $m_{-\varepsilon}(g_\varepsilon x^\alpha) \geq (1 + \varepsilon)x$. Therefore, by Lemma 4, for all sufficiently large x

$$\mathbb{P}[S_{-\varepsilon}(g_\varepsilon x^\alpha) > x] \geq 1 - \varepsilon.$$

Thus, replacing the last inequality and (20) in (19), we conclude that for all large x

$$\mathbb{P}[C > x] \geq \frac{(1 - \varepsilon)^2}{(1 + \varepsilon)^2} \int_{g_\varepsilon x^\alpha}^{\infty} \sum_{i=1}^{\infty} (q_i(1 + \varepsilon))^2 e^{-q_i(1+\varepsilon)t} dt. \quad (21)$$

In order to estimate the last integral, we observe that, by Lemma 2, for all $t \geq t_\varepsilon$

$$\sum_{i=1}^{\infty} (q_i(1 + \varepsilon))^2 e^{-q_i(1+\varepsilon)t} \geq (1 - \varepsilon) \frac{((1 + \varepsilon)c)^{1/\alpha}}{\alpha} \Gamma\left(2 - \frac{1}{\alpha}\right) t^{-2 + \frac{1}{\alpha}}.$$

Using this last estimate in (21) and computing the integral results in

$$\mathbb{P}[C > x] \geq \frac{(1 - \varepsilon)^3}{(1 + \varepsilon)^2} \frac{((1 + \varepsilon)c)^{\frac{1}{\alpha}}}{\alpha - 1} \Gamma\left(2 - \frac{1}{\alpha}\right) (g_\varepsilon x^\alpha)^{-1 + \frac{1}{\alpha}},$$

which, in conjunction with the definition of g_ε , yields, for all sufficiently large x

$$\mathbb{P}[C > x] \geq \frac{(1 - \varepsilon)^{4 - \frac{1}{\alpha}}}{(1 + 2\varepsilon)^{\alpha-1} (1 + \varepsilon)^{2 - \frac{1}{\alpha}}} K(\alpha) \frac{c}{(\alpha - 1)x^{\alpha-1}}.$$

The last bound and the asymptotic behavior of the request distribution $\mathbb{P}[R > x] \sim c/((\alpha - 1)x^{\alpha-1})$ further imply

$$\liminf_{x \rightarrow \infty} \frac{\mathbb{P}[C > x]}{\mathbb{P}[R > x]} \geq \frac{(1 - \varepsilon)^{4 - \frac{1}{\alpha}}}{(1 + 2\varepsilon)^{\alpha-1} (1 + \varepsilon)^{2 - \frac{1}{\alpha}}} K(\alpha),$$

which, by passing $\varepsilon \downarrow 0$, concludes the proof. \square

4.2. General modulation

In this section we prove our first main result for the general, stationary and ergodic, underlying process J , as defined in Section 2, with sufficiently fast rate of convergence of its empirical distribution.

Theorem 2. *If $q_i \sim c/i^\alpha$ as $i \rightarrow \infty$, $\alpha > 1$, and for any $\varepsilon > 0$*

$$\max_{1 \leq k \leq M} \mathbb{P}[|\hat{\pi}_k(t) - \pi_k| > \varepsilon] = o\left(t^{\frac{1}{\alpha}-2}\right) \quad \text{as } t \rightarrow \infty, \tag{22}$$

then

$$\mathbb{P}[C > x] \sim K(\alpha)\mathbb{P}[R > x] \quad \text{as } x \rightarrow \infty, \tag{23}$$

with $K(\alpha)$ as defined in (15).

Remark 4. This result and Theorem 3 of the following subsection show that LRU fault probability is asymptotically invariant under changes of the modulating process and behaves the same as in the case of i.i.d. requests with frequencies equal to the marginal distribution $\{q_i\}$. The constant $K(\alpha)$ is monotonically increasing in α with $\lim_{\alpha \rightarrow 1} K(\alpha) = 1$ and $\lim_{\alpha \rightarrow \infty} K(\alpha) = e^\gamma \approx 1.78$, where γ is the Euler constant; this was rigorously proved in Theorem 3 of [16]. \square

Remark 5. In order to illustrate the restriction imposed by condition (22), we consider a class of modulating processes J that are obtained by embedding a stationary and ergodic finite-state Markov chain into an independent stationary renewal process. Within this class, we show that condition (22) excludes those processes whose autocorrelation functions decay slower than $t^{(1/\alpha)-2}$, in particular long-range dependent modulating processes.

Consider a stationary renewal process $\{T_n, -\infty < n < \infty\}$, $T_0 \leq 0 < T_1$. The renewal intervals $\{T_n - T_{n-1}, n \neq 1\}$ are strictly positive i.i.d. variables with common distribution F having a finite mean μ , and are independent of the interval (T_0, T_1) . In order for this process to be stationary, the interval (T_0, T_1) that covers the origin has to have a special distribution, e.g. see Section 1.4.1 of [2] (see also Chapter 9 of [7]),

$$\mathbb{P}[-T_0 > y, T_1 > x] = \mu^{-1} \int_{x+y}^{\infty} (1 - F(u)) du, \tag{24}$$

this is often referred to as Feller’s paradox, and the distribution of T_1 is called the excess (residual) distribution of F . Next, let $\{\mathcal{J}_n\}$ be an irreducible and aperiodic finite-state Markov chain in stationary regime that is independent of the renewal process $\{T_n\}$. Now, we construct the modulating process J according to

$$J_t = \mathcal{J}_n \quad \text{for } T_n \leq t < T_{n+1}. \tag{25}$$

Suppose that for some $\beta > 0$, $d > 0$, the inter-arrival distribution satisfies $\mathbb{P}[T_2 - T_1 > t] \sim \mu d \beta / t^{1+\beta}$ as $t \rightarrow \infty$, implying, by (24),

$$\mathbb{P}[T_1 > t] \sim \frac{d}{t^\beta} \quad \text{as } t \rightarrow \infty.$$

Then, Theorem 7 of [17] shows that the autocorrelation function of J satisfies

$$\rho(t) \sim \mathbb{P}[T_1 > t] \quad \text{as } t \rightarrow \infty,$$

this implies that for $0 < \beta \leq 1$, $\int_1^\infty \rho(t) dt = \infty$, i.e., J is long-range dependent. On the other hand, since J_0 is independent of T_1 ,

$$\begin{aligned} \mathbb{P}[|\hat{\pi}_k(t) - \pi_k| > \varepsilon] &\geq \mathbb{P}[|\hat{\pi}_k(t) - \pi_k| > \varepsilon, T_1 > t] \\ &= \mathbb{P}[|1[J_0 = k] - \pi_k| > \varepsilon] \mathbb{P}[T_1 > t] \\ &\sim \frac{d_1}{t^\beta} \quad \text{as } t \rightarrow \infty, \end{aligned}$$

where $d_1 \triangleq d \mathbb{P}[|1[J_0 = k] - \pi_k| > \varepsilon]$. Therefore, when $\beta \leq 2 - (1/\alpha)$,

$$\liminf_{t \rightarrow \infty} (t^{2-\frac{1}{\alpha}} \mathbb{P}[|\hat{\pi}_k - \pi_k| > \varepsilon]) \geq \liminf_{t \rightarrow \infty} (d_1 t^{2-\frac{1}{\alpha}-\beta}) \geq d_1,$$

which violates condition (22). In particular, assumption (22) excludes the long-range dependent processes with $0 < \beta \leq 1$ since $2 - (1/\alpha) > 1$.

When the embedding renewal process is Poisson, the class of modulating processes J from (25) is equivalent to stationary and ergodic finite-state Markov processes. For Markov processes it is well known that, e.g. see Section 3.1.2 of [9], the empirical distribution $\hat{\pi}_k(t)$ converges exponentially fast to its stationary probability and, thus, estimate (22) holds. In general, by using the large deviation inequality from Corollary 1.6 of [21], it can be shown that, for the previously constructed class of processes, as defined in (25), condition (22) is satisfied when $\mathbb{E}(T_2 - T_1)^{1+\beta} < \infty$ for $\beta > 2 - (1/\alpha)$. We do not prove this claim since in the following subsection, using a different proof, we show in Theorem 3 that the asymptotic result from (23) holds for a more general class of semi-Markov processes. In particular, in the context of processes considered in this remark, Theorem 3 will show that the result (23) holds as long as $\mathbb{E}(T_2 - T_1)^{1+\beta} < \infty$ for any $\beta > 0$. Therefore, Theorem 3 extends to long-range dependent processes.

Proof of Theorem 2. By Proposition 2 and $\mathbb{P}[R > x] \sim c/((\alpha - 1)x^{\alpha-1})$ as $x \rightarrow \infty$, it suffices to prove

$$\limsup_{x \rightarrow \infty} (\mathbb{P}[C > x] x^{\alpha-1}) \leq K(\alpha) \frac{c}{\alpha - 1}.$$

Using $S(t; J) \equiv S_i(t; J) + B_i(t; J) \geq S_i(t; J)$ and the representation in (10), for any $h > 0$

$$\begin{aligned} \mathbb{P}[C > x] &\leq \mathbb{E} \int_0^{hx^2} \hat{f}(t) \mathbb{P}_{\sigma_t}[S(t; J) > x - 1] dt \\ &\quad + \mathbb{E} \int_{hx^2}^\infty \hat{f}(t) \mathbb{P}_{\sigma_t}[S(t; J) > x - 1] dt \\ &\triangleq I_1(x) + I_2(x), \end{aligned} \tag{26}$$

where

$$\hat{f}(t) \triangleq \sum_{i=1}^\infty q_i^{(J_0)} q_i^{(J_{-t})} e^{-\hat{q}_i t} \leq \sum_{i=1}^\infty q_i^{(J_0)} = 1. \tag{27}$$

Furthermore, the empirical distributions are uniformly bounded by $\hat{q}_i = \sum_{k=1}^M \hat{\pi}_k q_i^{(k)} \leq \sum_{k=1}^M q_i^{(k)} \leq \bar{q}_i \triangleq q_i / \min_k \pi_k < \infty$, since $\min_k \pi_k > 0$. Then, we define a sequence of independent Bernoulli random variables $\{\bar{B}_i(t), i \geq 1\}$, with $\mathbb{P}[\bar{B}_i(t) = 1] = 1 - e^{-\hat{q}_i t}$ and $\bar{S}(t) = \sum_{i=1}^{\infty} \bar{B}_i(t)$; similarly as in the proof of the lower bound, $\bar{S}(t)$ can be constructed non-decreasing in t . Note that for every ω , $\mathbb{P}_{\sigma_t}[B_i(t; J) = 1] \leq \mathbb{P}[\bar{B}_i(t) = 1]$ and, therefore, we obtain $\mathbb{P}_{\sigma_t}[S(t; J) > x - 1] \leq \mathbb{P}[\bar{S}(t) > x - 1]$ uniformly in ω . Using this observation and the monotonicity of $\bar{S}(t)$, we arrive at

$$I_1(x) \leq \int_0^{hx^\alpha} \mathbb{P}[\bar{S}(t) > x - 1] dt \leq hx^\alpha \mathbb{P}[\bar{S}(hx^\alpha) > x - 1]. \tag{28}$$

Now, due to Lemma 3, $\mathbb{E}\bar{S}(t) \leq Ht^{\frac{1}{\alpha}}$, and therefore, we can always find h small enough such that for any $\varepsilon > 0$ and all x large enough

$$\mathbb{E}\bar{S}(hx^\alpha) < (1 - \varepsilon)(x - 1). \tag{29}$$

Then, using (28), (29), Lemma 4 and setting $\varepsilon = \varepsilon/(1 - \varepsilon)$, we derive as $x \rightarrow \infty$

$$I_1(x) \leq Hx^\alpha e^{-h\theta_\varepsilon x} = o\left(\frac{1}{x^{\alpha-1}}\right). \tag{30}$$

Then, by using $v(t)$ as defined in (16), we obtain

$$\begin{aligned} I_2(x) &= \mathbb{E} \int_{hx^\alpha}^{\infty} \hat{f}(t) \mathbb{P}_{\sigma_t}[S(t; J) > x - 1] dt \\ &= \mathbb{E} \int_{hx^\alpha}^{\infty} \hat{f}(t) \mathbb{P}_{\sigma_t}[S(t; J) > x - 1] 1[v(t) \leq \varepsilon] dt \\ &\quad + \mathbb{E} \int_{hx^\alpha}^{\infty} \hat{f}(t) \mathbb{P}_{\sigma_t}[S(t; J) > x - 1] 1[v(t) > \varepsilon] dt \\ &\triangleq I_{21}(x) + I_{22}(x). \end{aligned} \tag{31}$$

Note that, by assumption of the theorem, for any $\delta > 0$ and t large enough, $\mathbb{P}[v(t) > \varepsilon] \leq \delta/t^{2-\frac{1}{\alpha}}$ and, therefore, using (27), for all x large enough

$$I_{22}(x) \leq \int_{hx^\alpha}^{\infty} \frac{\delta}{t^{2-1/\alpha}} dt = \frac{\delta}{(1 - \frac{1}{\alpha})h^{1-1/\alpha}x^{\alpha-1}}.$$

Thus, since δ can be arbitrarily small

$$I_{22}(x) = o\left(\frac{1}{x^{\alpha-1}}\right) \quad \text{as } x \rightarrow \infty. \tag{32}$$

Next, we will provide the estimate for $I_{21}(x)$. Similarly as in the proof of the lower bound, we define $S_\varepsilon(t) \triangleq \sum_{i=1}^{\infty} B_i^\varepsilon(t)$, where $\{B_i^\varepsilon(t), i \geq 1\}$ is a sequence of independent Bernoulli random variables with $\mathbb{P}[B_i^\varepsilon(t) = 1] = 1 - e^{-q_i(1+\varepsilon)t}$. As before, $S_\varepsilon(t)$ can be constructed non-decreasing in t . Therefore, by stochastic dominance, for every $\omega \in \{v(t) \leq \varepsilon\}$,

$$\mathbb{P}_{\sigma_t}[S(t; J) > x - 1] \leq \mathbb{P}[S_\varepsilon(t) > x - 1].$$

Furthermore, since for all ω in $\{v(t) \leq \varepsilon\}$ inequality (17) holds, by using (27) we obtain that for any constant $g_\varepsilon > 0$

$$\begin{aligned}
 I_{21}(x) &\leq \mathbb{E} \int_0^\infty \sum_{i=1}^\infty q_i^{(J_0)} q_i^{(J-t)} e^{-\hat{q}_i t} \mathbb{P}[S_\varepsilon(t) > x - 1] 1[v(t) \leq \varepsilon] dt \\
 &\leq \int_0^{g_\varepsilon x^\alpha} \mathbb{P}[S_\varepsilon(t) > x - 1] dt + \int_{g_\varepsilon x^\alpha}^\infty \sum_{i=1}^\infty \mathbb{E} \left[q_i^{(J_0)} q_i^{(J-t)} \right] e^{-(1-\varepsilon)q_i t} dt.
 \end{aligned}
 \tag{33}$$

If we select

$$g_\varepsilon = \frac{(1 - 2\varepsilon)^\alpha}{c(1 + \varepsilon)[\Gamma(1 - \frac{1}{\alpha})]^\alpha},$$

then, due to Lemma 3, $\mathbb{E}S_\varepsilon(g_\varepsilon x^\alpha) \sim (1 - 2\varepsilon)x$, which implies that for all x large enough ($x \geq x_\varepsilon$),

$$\mathbb{E}S_\varepsilon(g_\varepsilon x^\alpha) < (1 - \varepsilon)(x - 1).$$

Hence, since $S_\varepsilon(t)$ is non-decreasing, by using the previous inequality and applying Lemma 4 with $\varepsilon = \varepsilon/(1 - \varepsilon)$, we conclude that for x large

$$\begin{aligned}
 \int_0^{g_\varepsilon x^\alpha} \mathbb{P}[S_\varepsilon(t) > x - 1] dt &\leq g_\varepsilon x^\alpha \mathbb{P}[S_\varepsilon(g_\varepsilon x^\alpha) > x - 1] \\
 &\leq H x^\alpha e^{-\theta_\varepsilon(1-3\varepsilon)x} = o\left(\frac{1}{x^{\alpha-1}}\right).
 \end{aligned}
 \tag{34}$$

At this point, it remains to derive an estimate of the second integral in (33). Similarly as in the proof of the lower bound, since J satisfies (1), and has finitely many states, for all $i \geq 1$ and t large ($t \geq t_\varepsilon$)

$$\mathbb{E}[q_i^{(J_0)} q_i^{(J-t)}] \leq (1 + \varepsilon)q_i^2.$$

This implies that for x large enough, the second term in (33) is bounded by

$$\frac{1 + \varepsilon}{(1 - \varepsilon)^2} \int_{g_\varepsilon x^\alpha}^\infty \sum_{i=1}^\infty ((1 - \varepsilon)q_i)^2 e^{-(1-\varepsilon)q_i t} dt.$$

Bounding the preceding expression is analogous to evaluating the integral in (21), i.e., we use Lemma 2 to upper bound the sum under the integral for large x and then compute the integral for the chosen g_ε .

Therefore, combining the bound obtained in this way with (34), (33), (32), (31), (30), and (26), we derive

$$\limsup_{x \rightarrow \infty} (\mathbb{P}[C > x] x^{\alpha-1}) \leq \frac{(1 + \varepsilon)^{2-1/\alpha}}{(1 - 2\varepsilon)^{\alpha-1} (1 - \varepsilon)^{2-1/\alpha}} K(\alpha) \frac{c}{(\alpha - 1)},$$

which, by passing $\varepsilon \downarrow 0$, finishes the proof. \square

4.3. Semi-Markov modulation

In order to cover cases when condition (22) is not satisfied, e.g., those examples from Remark 5 that exhibit long-range dependence, we assume the following more specific structure of the modulating process. We consider the class of finite-state, stationary and ergodic semi-Markov processes J . In the following paragraph, we provide an explicit construction of such a process, which is similar to the one presented in Section 1.4.5 of [2] (for an alternative treatment of semi-Markov processes see Chapter 10 of [7]).

Let $\{p_{ij}\}$ be a stochastic matrix of an irreducible Markov chain with finitely many states M and unique stationary distribution $\{v_k\}$. For each $1 \leq k \leq M$, let F_k be the cumulative distribution function of some strictly positive and proper random variable ($F_k(0) = 0$ and $F_k(\infty) = 1$), having finite mean

$$\mu_k = \int_0^\infty (1 - F_k(t)) dt < \infty.$$

Next, we construct a point process $\{T_n, -\infty < n < \infty\}$, $T_0 \leq 0 < T_1$, on the same probability space. First, we construct variables $(T_0, T_1, \mathcal{J}_0)$ according to

$$\mathbb{P}[\mathcal{J}_0 = k, -T_0 > x, T_1 > y] = \frac{v_k}{\mu} \int_{x+y}^\infty (1 - F_k(u)) du, \quad x \geq 0, y \geq 0, \quad (35)$$

where $\mu \triangleq \sum_{k=1}^M v_k \mu_k$. Then, we construct a Markov sequence $\{\mathcal{J}_n, -\infty < n < \infty\}$ that is conditionally independent from the pair (T_0, T_1) given \mathcal{J}_0 . To this end, using the initial state \mathcal{J}_0 and the transition probabilities $\{p_{ij}\}$, we construct a sequence of Markov variables $\{\mathcal{J}_n, n \geq 0\}$; similarly, starting from the initial state \mathcal{J}_0 and the reversed transition probabilities $\{q_{ij} = p_{ji} v_j / v_i\}$, we create a Markov sequence $\{\mathcal{J}_n, n \leq 0\}$.

Now, let $\{U_n, -\infty < n < \infty\}$ be i.i.d. random variables on the same probability space that are uniformly distributed on $[0, 1]$ and independent from $\{\mathcal{J}_n\}$, T_0, T_1 . Then, given the already constructed $\{\mathcal{J}_n\}$, T_0, T_1 , the points T_n , for $n \geq 1$ and $n \leq -1$, respectively, are recursively defined by

$$\begin{aligned} T_{n+1} &= T_n + F_{\mathcal{J}_n}^{-1}(U_n) \quad \text{for } n \geq 1, \\ T_n &= T_{n+1} - F_{\mathcal{J}_n}^{-1}(U_n) \quad \text{for } n \leq -1, \end{aligned}$$

where $F_k^{-1}(\cdot)$ is the inverse of $F_k(\cdot)$. Finally, we define a semi-Markov process $J_t, t \in \mathbb{R}$, by

$$J_t = \mathcal{J}_n, \quad \text{for } T_n \leq t < T_{n+1}.$$

We also assume that J_t satisfies the asymptotic independence relation stated in (1), which follows from a mild assumption of $\{\mathcal{J}_n, (T_{n+1} - T_n)\}$ being aperiodic (see Theorem 6.12, p. 347 of [7]). We need this assumption in order to apply Proposition 2 for the lower bound. However, in the context of this section we would like to point out that assumption (1) can be omitted. This would require a different proof of the lower bound that uses analogous arguments to those that will be presented in Eqs. (68)–(69) of Section 7.

Here, we state some of the basic properties of the stationary semi-Markov process J that will be used in the remainder of the paper. From the preceding construction we see that at

each of the jump points T_n the next state of the semi-Markov process J as well as the length of the sojourn (holding) time $T_{n+1} - T_n$ are probabilistically determined by the current state J_{T_n} . Also, the intervals $\{T_{n+1} - T_n\}$ are conditionally independent given the process \mathcal{J} with the conditional distribution for $n \neq 0$ given by $\mathbb{P}[T_{n+1} - T_n \leq x | J_{T_n} = k] = F_k(x)$ and for $n = 0$ given by (35). The stationary distribution $\pi_k \triangleq \mathbb{P}[J_0 = k]$ of J satisfies $\pi_k = v_k \mu_k / \mu$. In addition, we note that when the sojourn times $T_{n+1} - T_n$ are exponentially distributed, the constructed process J is a Markov process. Furthermore, when $\{T_n, -\infty < n < \infty\}$ is a stationary renewal process and $\{\mathcal{J}_n\}$ is aperiodic, then the constructed J reduces to the class of processes described in Remark 5.

For J as described above, we state our second main result.

Theorem 3. *Assume that J is semi-Markov with $\max_k \mathbb{E}[(T_2 - T_1)^{1+\delta} | J_{T_1} = k] < \infty$, for some $\delta > 0$. If $q_i \sim c/i^\alpha$ as $i \rightarrow \infty$, $\alpha > 1$, then*

$$\mathbb{P}[C > x] \sim K(x) \mathbb{P}[R > x] \quad \text{as } x \rightarrow \infty,$$

with $K(x)$ as defined in (15).

In preparation for the proof we define the epochs of reversed jump points $\mathcal{T}_n \triangleq -T_{-n}$, $n \geq 0$; this notation is convenient since C of (10) depends on J_t for values of $t \leq 0$. In addition, the assumption $\max_k \mathbb{E}[(T_2 - T_1)^{1+\delta} | J_{T_1} = k] < \infty$, implies, for all $n \geq 0$,

$$\begin{aligned} \mathbb{E}(\mathcal{T}_{n+1} - \mathcal{T}_n)^{1+\delta} &\leq \sum_{k=1}^M \mathbb{E}[(\mathcal{T}_{n+1} - \mathcal{T}_n)^{1+\delta} | J_{-\mathcal{T}_{n+1}} = k] \\ &= \sum_{k=1}^M \mathbb{E}[(T_2 - T_1)^{1+\delta} | J_{T_1} = k] < \infty, \end{aligned} \tag{36}$$

and, by (35) and Markov’s inequality,

$$\mathbb{P}[\mathcal{T}_0 > x | J_0 = k] = \mathbb{P}[T_1 > x | J_0 = k] \leq \frac{H}{x^\delta} = o(1) \quad \text{as } x \rightarrow \infty, \tag{37}$$

this estimate will be used repeatedly in the proof of Theorem 3.

Heuristic outline of the proof: The lower bound follows from Proposition 2. Hence, in order to complete the proof, we need to prove the upper bound. To this end, we observe that $\hat{f}(t)$, as defined in (27), is a random variable measurable with respect to σ_t . Therefore, using $S(t; J) \geq S_i(t; J)$ and $\mathbb{P}_{\sigma_t}[S(t; J) > x] = \mathbb{E}_{\sigma_t}[1[S(t; J) > x]]$, the integral representation in (10) is bounded by

$$\begin{aligned} \mathbb{P}[C > x] &\leq \mathbb{E} \int_0^\infty \hat{f}(t) 1[S(t; J) > x - 1] dt \\ &= \mathbb{E} \int_0^{\mathcal{T}_0} + \mathbb{E} \int_{\mathcal{T}_0}^{\mathcal{T}_{\lfloor x^{1/3} \rfloor}} + \mathbb{E} \int_{\mathcal{T}_{\lfloor x^{1/3} \rfloor}}^\infty \\ &\triangleq I_1(x) + I_2(x) + I_3(x). \end{aligned} \tag{38}$$

For a given initial state $J_0 = k$, the integral representation in $I_1(x)$ approximately corresponds to the case of i.i.d. requests, represented in (11), where q_i is replaced by $q_i^{(k)}$ and the

integration is truncated by a random time \mathcal{T}_0 . Thus, if we condition on \mathcal{T}_0 being respectively greater or smaller than hx^α with appropriately chosen h we derive

$$I_1(x) \lesssim \sum_{k=1}^M \int_0^\infty \sum_{i=1}^\infty (q_i^{(k)})^2 e^{-q_i^{(k)}t} \mathbb{P}[S_i^{(k)}(t) > x - 2] \mathbb{P}[J_0 = k, \mathcal{T}_0 > hx^\alpha] dt + \int_0^{hx^\alpha} \mathbb{P}[\bar{S}(t) > x - 1] dt.$$

In the preceding bound, if we use the fact that $\mathbb{P}[\mathcal{T}_0 > x] \rightarrow 0$ as $x \rightarrow \infty$ and Lemma 5 in the first term, and the monotonicity of $\bar{S}(t)$ and Lemma 4 in the second integral term, we estimate $I_1(x) = o(1/x^{\alpha-1})$ as $x \rightarrow \infty$.

Next, observe that, for x large enough, $\mathcal{T}_{\lfloor x^{1/3} \rfloor} \approx x^{1/3}\mu$. Then, by using $\hat{f}(t) \leq 1$ and the definition of $\bar{S}(t)$ from the proof of Theorem 2, we conclude

$$I_2(x) \lesssim \int_0^{x^{1/3}\mu} \mathbb{P}[\bar{S}(t) > x - 1] dt \leq x^{1/3}\mu \mathbb{P}[\bar{S}(x^{1/3}\mu) > x - 1] = o\left(\frac{1}{x^{\alpha-1}}\right) \text{ as } x \rightarrow \infty,$$

where in the last equality we exploited Lemmas 3 and 4.

Finally, due to ergodicity of the process J , for t large enough $\hat{q}_i \approx q_i$ and, therefore, from the definitions of $B_i(t; J)$ and $S(t; J)$, we deduce that $S(t; J) \approx S(t)$, where $S(t)$ corresponds to the number of distinct requests in $[-t, 0)$ for the case of i.i.d. requests with distribution q_i , as defined in Section 3.2. Hence, for x large enough, $I_3(x)$ is approximately

$$I_3(x) \approx \mathbb{E} \int_{x^{1/3}\mu}^\infty \hat{f}(t) 1[S(t; J) > x - 1] dt \approx \int_{x^{1/3}\mu}^\infty \sum_{i=1}^\infty e^{-q_i t} \mathbb{E}[q_i^{(J_0)} q_i^{(J_{-t})}] \mathbb{P}[S(t) > x - 1] dt \approx \int_0^\infty \sum_{i=1}^\infty e^{-q_i t} q_i^2 \mathbb{P}[S_i(t) > x - 2] dt,$$

since, by (1), $\mathbb{E}[q_i^{(J_0)} q_i^{(J_{-t})}] \approx q_i^2$ and $S_i(t) \geq S(t) - 1$. The last displayed expression is equal to the case of i.i.d. requests stated in Eq. (11) (with x replaced by $x - 1$) and can be estimated using either Theorem 3 of [16] or our Theorem 2. A rigorous proof of the theorem is much more involved and very technical and, therefore, we present it in the separate Section 7 of this paper.

5. Numerical examples

In this subsection, we provide three simulation experiments that illustrate Theorems 2 and 3. We consider the case where the underlying process J_t is a two-state ($\{0, 1\}$) semi-Markov process with parameters implying strong correlation. Since the asymptotic

Fig. 1. Illustration for Example 1.

results were obtained first by passing the list size N to infinity and then investigating the tail of the limiting search cost distribution, it can be expected that the asymptotic expression gives a reasonable approximation for $\mathbb{P}[C^N > k]$ when both N and k are large (with N much larger than k). However, it is surprising how accurately the approximation works even for relatively small values of N and almost all values of $k < N$.

In each experiment, before we conduct measurements, we allow 10^7 units of warm-up time (approximately $n \approx 10^7$ requests) for the system to reach stationarity; our preliminary experiments showed that using larger delays did not lead to improved results. In addition, we increase the accuracy of each simulation by running each experiment from two different initial positions of the list. We select these initial positions uniformly at random and according to the inverse order of the items popularity. In all experiments, the measured results are almost identical for these different initial conditions. The actual measurement time is set to be 10^7 units long. In all the experiments, the measurements are conducted for cache sizes $k = 50j$, $1 \leq j \leq 16$, and are presented with star “*” symbols in Figs. 1–3, while our approximation, $K(\alpha)\mathbb{P}[R > k]$, is represented with the solid line on the same figures.

The total number of documents in all three experiments is set to $N = 1000$. The Markovian transitions of the two-state modulating process are $p_{01} = p_{10} = 1$. We use τ^0 and τ^1 to denote the variables equal in distribution to the sojourn times corresponding to states 0 and 1, respectively. In the first two experiments τ^0 and τ^1 are discrete random variables, while in the third experiment they are continuous.

Example 1. In this experiment we choose discrete random variables τ^0 and τ^1 to be distributed as $\mathbb{P}[\tau^1 = 10i] = \mathbb{P}[\tau^0 = 10i] = a(1/(10i)^3 - 1/(10(i+1))^3)$, where

Fig. 2. Illustration for Example 2.

$i \in \{1, \dots, 10^4\}$ and $a = 10^3(1 - 1/(10^4 + 1)^3)^{-1}$. In state 0, only odd items are requested according to $q_{2i+1}^{(0)} = H_N^0/(2i+1)^{1.4}$ ($i = 0, 1, \dots, 499$), $q_{2i}^{(0)} = 0$ ($i = 1, \dots, 500$), where $1/H_N^0 = \sum_{i=0}^{499} 1/(2i+1)^{1.4}$, while in state 1, the probabilities are concentrated exclusively on even documents, $q_{2i}^{(1)} = H_N^1/(2i)^{1.4}$ ($i = 1, \dots, 500$), $q_{2i+1}^{(1)} = 0$ ($i = 0, 1, \dots, 499$), where $1/H_N^1 = \sum_{i=1}^{500} 1/(2i)^{1.4}$. The experimental results are presented in Fig. 1. This model corresponds to the case where two different classes of clients request documents from disjoint sets. Even in this extreme scenario, our approximation $K(\alpha)\mathbb{P}[R > k]$ matches very precisely the simulated results.

Example 2. Here, we select variables τ^0 and τ^1 to be distributed as $\mathbb{P}[\tau^1 = 10i] = \mathbb{P}[\tau^0 = 10i] = b(1/(10i)^{0.8} - 1/(10(i+1))^{0.8})$, where $i \in \{1, \dots, 10^4\}$ and $b = 10^{0.8}(1 - 1/(10^4 + 1)^{0.8})^{-1}$. In state 0, items are requested according to distribution $q_i^{(0)} = H_N^0/i^{1.4}$, where $1/H_N^0 = \sum_{i=1}^N 1/i^{1.4}$, and in state 1, the popularity of documents is given by $q_i^{(1)} = H_N^1/i^4$, where $1/H_N^1 = \sum_{i=1}^N 1/i^4$. Our intention in this experiment is to show that only the heavier tailed probability distribution impacts the LRU performance. This follows from our asymptotic results and the fact that for large k , $k \ll N$, $\mathbb{P}[R > k] \approx 1.25H_N^0/k^{0.4}$, i.e. the marginal distribution is dominated by the heavier tailed probability distribution $q_i^{(0)}$. The simulation results in this case are presented in Fig. 2. As in the preceding experiment, we obtain accurate agreement between the approximation and simulation.

Fig. 3. Illustration for Example 3.

Example 3. Now, we illustrate the case where $\mathbb{P}[\tau^1 > t] = e^{-3t}$, $t \in [0, \infty)$ (exponential distribution) and $\mathbb{P}[\tau^0 \geq t] = 1/t^{0.8}$, $t \in [1, 10^5]$ and $\mathbb{P}[\tau^0 \geq t] = 0$ for $t > 10^5$. In state 0, items are requested according to distribution $q_i^{(0)} = H_N^0/i^3$, where $1/H_N^0 = \sum_{i=1}^N 1/i^3$. In state 1, the popularity of documents is $q_i^{(1)} = H_N^1/i^{1.4}$, where $1/H_N^1 = \sum_{i=1}^N 1/i^{1.4}$. This experiment shows that even in the case when $\mathbb{E}\tau^0 = 46 \gg \mathbb{E}\tau^1 = 1/3$, the tail of the search cost distribution is asymptotically dominated by the heavier tail of requests in state 1. Again, the excellent agreement of the approximation with simulated results is apparent from Fig. 3.

6. Concluding remarks

In this paper we investigated the asymptotic behavior of the LRU cache fault probability, or equivalently the MTF search cost distribution, for a class of semi-Markov modulated request processes. This class of processes provides both the analytical tractability and flexibility of modeling a wide range of statistical correlations, including the empirically measured long-range dependence (see [1]). When the marginal probability mass function of requests follows generalized Zipf's law, our main results show that the LRU fault probability is asymptotically proportional to the tail of the request distribution. These results assume the same form as recently developed asymptotics for i.i.d. requests [16], implying that the LRU cache fault probability is invariant to changes to the underlying, possibly strong, dependency structure in the document request sequence. This surprising insensitivity suggests

that one may not need to model accurately, if at all, the statistical correlation in the request sequence. Hence, this may simplify the modeling process of the Web access patterns and further improve the speed of simulating network caching systems.

Our results are further validated using simulation. The excellent agreement between the analytical and experimental results implies the potential use of our approximation in predicting the performance and properly engineering Web caches. The explicit nature, high degree of accuracy, and low computational complexity of our result contrast the lengthy procedure of simulation experiments.

7. Proof of Theorem 3

In order to prove the theorem we will need the following technical lemma. Recall the definition of \mathcal{T}_n from Section 4.3.

Lemma 7. *If $\max_k \mathbb{E}[(\mathcal{T}_1 - \mathcal{T}_0)^{1+\delta} | J_{-\mathcal{T}_1} = k] < \infty$, then there exists $s > 0$ such that, uniformly for all $n \leq sx$,*

$$n^{-1} \mathbb{P}[\mathcal{T}_n - \mathcal{T}_0 > x] \leq o\left(\frac{1}{x^{1+\delta}}\right) \quad \text{as } x \rightarrow \infty.$$

Proof of Lemma 7. We construct a sequence $\{X_i, i \leq n\}$ of i.i.d. random variables with

$$\bar{F}(x) \triangleq \mathbb{P}[X_i > x] = \max_{1 \leq k \leq M} (1 - F_k(x)),$$

where $F_k(x)$, $1 \leq k \leq M$, is defined at the beginning of Section 4.3. Therefore, $\mathbb{P}[X_i > x] \geq \mathbb{P}[\mathcal{T}_i - \mathcal{T}_{i-1} > x | J_{-\mathcal{T}_i}]$ and

$$\begin{aligned} \mathbb{P}[\mathcal{T}_n - \mathcal{T}_0 > x] &= \mathbb{P}\left[\sum_{i=1}^n (\mathcal{T}_i - \mathcal{T}_{i-1}) > x\right] \\ &= \mathbb{E}\left[\mathbb{P}\left[\sum_{i=1}^n (\mathcal{T}_i - \mathcal{T}_{i-1}) > x \mid J_{-\mathcal{T}_j}, 1 \leq j \leq n\right]\right] \\ &\leq \mathbb{P}\left[\sum_{i=1}^n X_i > x\right] = \mathbb{P}\left[\sum_{i=1}^n X_i - n\mathbb{E}X_1 > x - n\mathbb{E}X_1\right]. \end{aligned}$$

Now, since $\max_k \mathbb{E}[(\mathcal{T}_1 - \mathcal{T}_0)^{1+\delta} | J_{-\mathcal{T}_1} = k] < \infty$, we conclude $\mathbb{E}X_1^{1+\varepsilon} < H < \infty$, for any $0 \leq \varepsilon \leq \delta$ and some large constant H and therefore, uniformly for all $n \leq sx$, we obtain

$$\mathbb{P}[\mathcal{T}_n - \mathcal{T}_0 > x] \leq \mathbb{P}\left[\sum_{i=1}^n X_i - n\mathbb{E}X_1 > x - sHx\right].$$

Now, by taking $s > 0$ such that $sH = 1/2$ and applying Corollary 1.6 of [21] we conclude the proof. \square

Proof of Theorem 3. In view of the heuristic outline of the proof from Section 4.3, we proceed by deriving the upper bounds for the expressions $I_j(x)$ defined in (38). In order to

estimate $I_1(x)$, we first condition on \mathcal{T}_0 being respectively greater or smaller than hx^α :

$$\begin{aligned} I_1(x) &= \mathbb{E} \int_0^{\mathcal{T}_0} \sum_{i=1}^{\infty} (q_i^{(J_0)})^2 e^{-q_i^{(J_0)} t} 1[S(t; J) > x - 1] dt \\ &\leq \mathbb{E} \int_0^{\mathcal{T}_0} \sum_{i=1}^{\infty} (q_i^{(J_0)})^2 e^{-q_i^{(J_0)} t} 1[S(t; J) > x - 1] 1[\mathcal{T}_0 > hx^\alpha] dt \\ &\quad + \mathbb{E} \int_0^{\mathcal{T}_0} 1[S(t; J) > x - 1] 1[\mathcal{T}_0 \leq hx^\alpha] dt \\ &\triangleq I_{11}(x) + I_{12}(x). \end{aligned}$$

Next, we define $S_i^{(k)}(t) \triangleq \sum_{j \neq i} B_j^{(k)}(t)$, $S^{(k)}(t) = S_i^{(k)}(t) + B_i^{(k)}(t)$, where $\{B_i^{(k)}(t), i \geq 1\}$ is a sequence of independent Bernoulli random variables with $\mathbb{P}[B_i^{(k)}(t) = 1] = 1 - e^{-q_i^{(k)} t}$. Then, from the definition of $S(t; J)$ it follows that $\mathbb{P}[S(t; J) > x | J_0 = k, t < \mathcal{T}_0] = \mathbb{P}[S^{(k)}(t) > x]$. Thus, using this fact, $q_i^{(k)} \leq \bar{q}_i \leq H/i^\alpha$, Lemma 5, and Eq. (37), we obtain

$$\begin{aligned} I_{11}(x) &\leq \sum_{k=1}^M \mathbb{P}[J_0 = k, \mathcal{T}_0 > hx^\alpha] \int_0^{\infty} \sum_{i=1}^{\infty} (q_i^{(k)})^2 e^{-q_i^{(k)} t} \mathbb{P}[S_i^{(k)}(t) > x - 2] dt \\ &\leq M \mathbb{P}[\mathcal{T}_0 > hx^\alpha] \frac{H}{x^{\alpha-1}} = o\left(\frac{1}{x^{\alpha-1}}\right) \quad \text{as } x \rightarrow \infty. \end{aligned} \quad (39)$$

In estimating $I_{12}(x)$ we use $\mathcal{T}_0 \leq hx^\alpha$ and exactly the same arguments as in (28)–(30), rendering

$$I_{12}(x) \leq hx^\alpha \mathbb{P}[\bar{S}(hx^\alpha) > x - 1] = o\left(\frac{1}{x^{\alpha-1}}\right) \quad \text{as } x \rightarrow \infty.$$

Thus, the preceding bound and (39) imply

$$I_1(x) = o\left(\frac{1}{x^{\alpha-1}}\right) \quad \text{as } x \rightarrow \infty. \quad (40)$$

At this point, we provide an estimate for $I_2(x)$. If we define

$$I_n^*(x) \triangleq \mathbb{E} \int_{\mathcal{T}_{n-1}}^{\mathcal{T}_n} \hat{f}(t) 1[S(\mathcal{T}_n; J) > x - 1] dt,$$

then

$$I_2(x) \leq \sum_{n=1}^{\lfloor x^{1/3} \rfloor} I_n^*(x) \quad (41)$$

and

$$I_n^*(x) = \mathbb{E} \int_{\mathcal{T}_{n-1}}^{\mathcal{T}_n} \hat{f}(t) 1[\mathcal{T}_0 > hx^\alpha] 1[S(\mathcal{T}_n; J) > x - 1] dt$$

$$\begin{aligned}
 & + \mathbb{E} \int_{\mathcal{T}_{n-1}}^{\mathcal{T}_n} \hat{f}(t) 1[\mathcal{T}_0 \leq hx^\alpha] 1[S(\mathcal{T}_n; J) > x - 1] dt \\
 & \triangleq I_{n,1}^*(x) + I_{n,2}^*(x).
 \end{aligned}$$

Next, when we replace the bound

$$\hat{f}(t) \leq \sum_{i=1}^{\infty} q_i^{(J_0)} q_i^{(J-\mathcal{T}_n)} e^{-q_i^{(J_0)} \mathcal{T}_0} e^{-q_i^{(J-\mathcal{T}_n)} (t-\mathcal{T}_{n-1})} \quad \text{for } t \in (\mathcal{T}_{n-1}, \mathcal{T}_n] \tag{42}$$

in $I_{n,1}^*(x)$ and evaluate the integral, we derive

$$I_{n,1}^*(x) \leq \mathbb{E} \sum_{i=1}^{\infty} 1[\mathcal{T}_0 > hx^\alpha] q_i^{(J_0)} e^{-q_i^{(J_0)} hx^\alpha} (1 - e^{-q_i^{(J-\mathcal{T}_n)} (\mathcal{T}_n - \mathcal{T}_{n-1})}).$$

Then, using $1 - e^{-x} \leq x$ for $x \geq 0$, $\max(q_i^{(J_0)}, q_i^{(J-\mathcal{T}_n)}) \leq \bar{q}_i \leq H/i^\alpha$ and $\sup_{y \geq 0} ye^{-y} = e^{-1}$, similarly as in (13), we arrive at

$$\begin{aligned}
 I_{n,1}^*(x) & \leq \mathbb{E} \sum_{i=1}^x \frac{e^{-1} 1[\mathcal{T}_0 > hx^\alpha]}{hx^\alpha} \bar{q}_i (\mathcal{T}_n - \mathcal{T}_{n-1}) \\
 & \quad + \mathbb{E} \sum_{i=x}^{\infty} 1[\mathcal{T}_0 > hx^\alpha] (\bar{q}_i)^2 (\mathcal{T}_n - \mathcal{T}_{n-1}) \\
 & \leq \mathbb{E}[(\mathcal{T}_n - \mathcal{T}_{n-1}) 1[\mathcal{T}_0 > hx^\alpha]] \frac{H}{x^\alpha}.
 \end{aligned} \tag{43}$$

Since the random variables $(\mathcal{T}_n - \mathcal{T}_{n-1}), n \geq 1$, and $1[\mathcal{T}_0 > hx^\alpha]$ are conditionally independent given J_0 , we derive

$$\begin{aligned}
 & \mathbb{E}[(\mathcal{T}_n - \mathcal{T}_{n-1}) 1[\mathcal{T}_0 > hx^\alpha]] \\
 & = \mathbb{E}[\mathbb{E}[\mathcal{T}_n - \mathcal{T}_{n-1} | J_0] \mathbb{P}[\mathcal{T}_0 > hx^\alpha | J_0]] \\
 & \leq \left(\max_{1 \leq k \leq M} \mathbb{E}[\mathcal{T}_n - \mathcal{T}_{n-1} | J_0 = k] \right) \mathbb{P}[\mathcal{T}_0 > hx^\alpha] \\
 & \leq \left(\max_{1 \leq k \leq M} \mu_k \right) \mathbb{P}[\mathcal{T}_0 > hx^\alpha].
 \end{aligned} \tag{44}$$

Thus, the preceding bound, (43), and (37) yield, uniformly in n ,

$$I_{n,1}^*(x) = o\left(\frac{1}{x^\alpha}\right) \quad \text{as } x \rightarrow \infty. \tag{45}$$

Next, we compute an estimate for $I_{n,2}^*(x)$. Using (42) and computing the integral in $I_{n,2}^*(x)$ result in

$$\begin{aligned}
 I_{n,2}^*(x) & \leq \mathbb{E} \sum_{i=1}^{\infty} 1[\mathcal{T}_0 \leq hx^\alpha, S(\mathcal{T}_n; J) > x - 1] q_i^{(J_0)} e^{-q_i^{(J_0)} \mathcal{T}_0} \\
 & \quad \times (1 - e^{-q_i^{(J-\mathcal{T}_n)} (\mathcal{T}_n - \mathcal{T}_{n-1})}) \\
 & \leq \mathbb{P}[\mathcal{T}_0 \leq hx^\alpha, S(\mathcal{T}_n; J) > x - 1]
 \end{aligned}$$

$$\begin{aligned} &\leq \mathbb{P}[S(\mathcal{T}_n; J) > x - 1, \mathcal{T}_0 \leq hx^\alpha, S(\mathcal{T}_0; J) \leq \varepsilon x - 1] \\ &\quad + \mathbb{P}[\mathcal{T}_0 \leq hx^\alpha, \bar{S}(\mathcal{T}_0) > \varepsilon x - 1], \end{aligned} \tag{46}$$

since $\bar{S}(t)$ stochastically dominates $S(t; J)$. Let $S(u, t; J)$, $0 < u < t$, be the number of distinct items requested in $[-t, -u)$; then, it is easy to see that $S(\mathcal{T}_n; J) \leq S(\mathcal{T}_0; J) + S(\mathcal{T}_0, \mathcal{T}_n; J)$. Thus, if we choose h small enough such that $\mathbb{E}\bar{S}(hx^\alpha) \leq (\varepsilon x - 1)/(1 + \varepsilon)$ for large x , then, by Lemma 4, we obtain ($x \geq x_\varepsilon$)

$$\begin{aligned} I_{n,2}^*(x) &\leq \mathbb{P}[S(\mathcal{T}_0, \mathcal{T}_n; J) > (1 - \varepsilon)x] + \mathbb{P}[\bar{S}(hx^\alpha) > \varepsilon x - 1] \\ &\leq \mathbb{P}[\bar{S}(\mathcal{T}_n - \mathcal{T}_0) > (1 - \varepsilon)x] + H e^{-h\theta_\varepsilon x}. \end{aligned} \tag{47}$$

Now, if we pick h small enough such that $\mathbb{E}\bar{S}(hx^\alpha) < x(1 - \varepsilon)/(1 + \varepsilon)$ for all large x , we obtain that, uniformly for all $n \leq x^{1/3}$,

$$\begin{aligned} &\mathbb{P}[\bar{S}(\mathcal{T}_n - \mathcal{T}_0) > (1 - \varepsilon)x] \\ &\leq \mathbb{P}[\bar{S}(hx^\alpha) > (1 - \varepsilon)x] + \mathbb{P}[\mathcal{T}_n - \mathcal{T}_0 > hx^\alpha] \\ &\leq \mathbb{P}[\bar{S}(hx^\alpha) > (1 - \varepsilon)x] + \sum_{i=1}^n \mathbb{P}\left[\mathcal{T}_i - \mathcal{T}_{i-1} > \frac{hx^\alpha}{n}\right] \\ &\leq H e^{-h\theta_\varepsilon x} + o\left(\frac{1}{x^{\alpha-2/3}}\right) \quad \text{as } x \rightarrow \infty, \end{aligned} \tag{48}$$

where in the second inequality we used the union bound, and in the last expression Lemma 4, (36) and Markov’s inequality. This implies $I_{n,2}^*(x) = o(1/x^{\alpha-2/3})$ as $x \rightarrow \infty$, uniformly for all $n \leq x^{1/3}$. Therefore, in conjunction with (45) and (41), we derive

$$I_2(x) = o\left(\frac{1}{x^{\alpha-1}}\right) \quad \text{as } x \rightarrow \infty. \tag{49}$$

In order to derive asymptotics for $I_3(x)$, we use the fact that the semi-Markov process J observed at its jump points $\{J_{-\mathcal{T}_n}, n \geq 0\}$ is a Markov chain. Define the amount of time that J spends in state k in $\mathcal{T}_{0,n} \equiv (-\mathcal{T}_n, -\mathcal{T}_0)$ as

$$\tau_k(\mathcal{T}_{0,n}) \triangleq \sum_{i=0}^{n-1} 1_{[J_{-\mathcal{T}_{i+1}} = k]}(\mathcal{T}_{i+1} - \mathcal{T}_i),$$

Then, by ergodicity of the Markov chain $\{J_{-\mathcal{T}_i}\}$, as $n \rightarrow \infty$,

$$\begin{aligned} \mathbb{E}\tau_k(\mathcal{T}_{0,n}) &= \sum_{i=0}^{n-1} \mathbb{P}[J_{-\mathcal{T}_{i+1}} = k] \mathbb{E}[\mathcal{T}_{i+1} - \mathcal{T}_i | J_{-\mathcal{T}_{i+1}} = k] \\ &\sim n v_k \mu_k = n \mu \pi_k. \end{aligned} \tag{50}$$

For any $1 \leq k \leq M$, a well-known large deviation result on finite state ergodic Markov chains (e.g., see Section 3.1.2 of [9]) shows that for any $\varepsilon > 0$, there is $\theta_{k,\varepsilon} > 0$, such that the number of times $N_n(k)$ that $J_{-\mathcal{T}_i}$ visits state k for $1 \leq i \leq n$, i.e. $N_n(k) = \sum_{i=1}^n 1_{[J_{-\mathcal{T}_i} = k]}$, satisfies

$$\mathbb{P}[|N_n(k) - v_k n| > \varepsilon n] \leq e^{-\theta_{k,\varepsilon} n}. \tag{51}$$

Next, let $\{\mathcal{T}_i(k)\}$ be i.i.d. random variables that are independent of $N_n(k)$ and have a common distribution equal to $F_k(x) = \mathbb{P}[\mathcal{T}_1 - \mathcal{T}_0 \leq x | J_{-\mathcal{T}_1} = k]$. Then, it is easy to see that $\tau_k(\mathcal{T}_{0,n})$ is equal in distribution to $\sum_{i=1}^{N_n(k)} \mathcal{T}_i(k)$, and, by (50), for all n large $\mathbb{E}\tau_k(\mathcal{T}_{0,n}) < (1 + \varepsilon)\mu_k v_k n$,

implying

$$\begin{aligned} & \mathbb{P}[\tau_k(\mathcal{T}_{0,n}) < (1 - \varepsilon)\mathbb{E}\tau_k(\mathcal{T}_{0,n})] \\ & \leq \mathbb{P}\left[\sum_{i=1}^{N_n(k)} \mathcal{T}_i(k) < (1 - \varepsilon^2)\mu_k v_k n\right] \\ & \leq \mathbb{P}\left[N_n(k) < \left(1 - \frac{\varepsilon^2}{2}\right)v_k n\right] + \mathbb{P}\left[\sum_{i=1}^{(1-(\varepsilon^2/2))v_k n} (\mu_k - \mathcal{T}_i(k)) > \frac{\varepsilon^2}{2}v_k \mu_k n\right]. \end{aligned} \tag{52}$$

Since the random variables $\mu_k - \mathcal{T}_i(k)$ are bounded from the right ($\mu_k - \mathcal{T}_i(k) \leq \mu_k$), using a large deviation (Chernoff) bound, e.g. see Theorem 1.5, p. 14 of [26], we conclude that the second term in (52) is exponentially bounded, and, in conjunction with (51), we arrive at

$$\mathbb{P}[\tau_k(\mathcal{T}_{0,n}) < (1 - \varepsilon)\mathbb{E}\tau_k(\mathcal{T}_{0,n})] \leq e^{-\theta_\varepsilon n}, \tag{53}$$

for some $\theta_\varepsilon > 0$. Therefore, the probability of the complement of the set

$$\mathcal{A}(n) \triangleq \bigcap_{1 \leq k \leq M} \{\tau_k(\mathcal{T}_{0,n}) \geq (1 - \varepsilon)n\mu_k v_k\}$$

is exponentially bounded: $\mathbb{P}[\mathcal{A}^c(n)] \leq M e^{-\theta_\varepsilon n}$.

At this point, using the bounds from the preceding paragraph, we estimate $I_3(x)$ by decomposing it as

$$\begin{aligned} I_3(x) & \leq \mathbb{E} \sum_{n=\lfloor x^{1/3} \rfloor}^{\infty} \int_{\mathcal{T}_n}^{\mathcal{T}_{n+1}} \hat{f}(t) 1[\mathcal{A}^c(n)] dt \\ & \quad + \mathbb{E} \sum_{n=\lfloor x^{1/3} \rfloor}^{\infty} \int_{\mathcal{T}_n}^{\mathcal{T}_{n+1}} \hat{f}(t) 1[S(t; J) > x - 1] 1[\mathcal{A}(n)] dt. \end{aligned} \tag{54}$$

Now, replacing (42) in the first expression of the preceding inequality, computing the integral and bounding it by 1, and, then, using the exponential bound on $\mathbb{P}[\mathcal{A}^c(n)]$ lead to

$$\mathbb{E} \sum_{n=\lfloor x^{1/3} \rfloor}^{\infty} 1[\mathcal{A}^c(n)] \int_{\mathcal{T}_n}^{\mathcal{T}_{n+1}} \hat{f}(t) dt \leq \sum_{n=\lfloor x^{1/3} \rfloor}^{\infty} \mathbb{P}[\mathcal{A}^c(n)] = o\left(\frac{1}{x^{\alpha-1}}\right) \quad \text{as } x \rightarrow \infty.$$

Hence, applying the preceding estimate in (54) and conditioning on the length of \mathcal{T}_0 imply, as $x \rightarrow \infty$,

$$\begin{aligned} I_3(x) & \leq \mathbb{E} \sum_{n=\lfloor x^{1/3} \rfloor}^{\infty} \int_{\mathcal{T}_n}^{\mathcal{T}_{n+1}} \hat{f}(t) 1[S(t; J) > x - 1, \mathcal{T}_0 > hx^\alpha, \mathcal{A}(n)] dt \\ & \quad + \mathbb{E} \sum_{n=\lfloor x^{1/3} \rfloor}^{\infty} \int_{\mathcal{T}_n}^{\mathcal{T}_{n+1}} \hat{f}(t) 1[S(t; J) > x - 1, \mathcal{T}_0 \leq hx^\alpha, \mathcal{A}(n)] dt \\ & \quad + o\left(\frac{1}{x^{\alpha-1}}\right) \\ & \triangleq I_{31}(x) + I_{32}(x) + o\left(\frac{1}{x^{\alpha-1}}\right). \end{aligned} \tag{55}$$

Next, in estimating $I_{31}(x)$, note that for all $\omega \in \mathcal{A}(n)$

$$\sum_{k=1}^M \tau_k(\mathcal{T}_{0,n}) q_i^{(k)} \geq (1 - \varepsilon)n \sum_{k=1}^M q_i^{(k)} \nu_k \mu_k = (1 - \varepsilon)n\mu \sum_{k=1}^M q_i^{(k)} \pi_k = (1 - \varepsilon)n\mu q_i,$$

and therefore, for $t \in (\mathcal{T}_n, \mathcal{T}_{n+1}]$,

$$\hat{f}(t)1[\mathcal{A}(n)] \leq \sum_{i=1}^{\infty} q_i^{(J_0)} q_i^{(J-\mathcal{T}_{n+1})} e^{-q_i^{(J_0)}\mathcal{T}_0} e^{-\mu n q_i (1-\varepsilon)} e^{-q_i^{(J-\mathcal{T}_{n+1})}(t-\mathcal{T}_n)} 1[\mathcal{A}(n)]. \quad (56)$$

Therefore, by using (56) in $I_{31}(x)$, then completing the integration and applying $1 - e^{-x} \leq x$, $x \geq 0$, we derive

$$\begin{aligned} I_{31}(x) &\leq \mathbb{E} \sum_{n=\lfloor x^{1/3} \rfloor}^{\infty} \int_{\mathcal{T}_n}^{\mathcal{T}_{n+1}} \hat{f}(t)1[\mathcal{T}_0 > hx^\alpha, \mathcal{A}(n)] dt \\ &\leq \mathbb{E} \sum_{n=\lfloor x^{1/3} \rfloor}^{\infty} \sum_{i=1}^{\infty} e^{-\mu n q_i (1-\varepsilon)} q_i^{(J_0)} e^{-q_i^{(J_0)} hx^\alpha} q_i^{(J-\mathcal{T}_{n+1})} 1[\mathcal{T}_0 > hx^\alpha] (\mathcal{T}_{n+1} - \mathcal{T}_n) \\ &\leq H \mathbb{E} \left[1[\mathcal{T}_0 > hx^\alpha] \sum_{i=1}^{\infty} q_i^{(J_0)} e^{-q_i^{(J_0)} hx^\alpha} \right], \end{aligned}$$

where the last inequality uses double conditioning, $\mathbb{E}[\mathcal{T}_{n+1} - \mathcal{T}_n | J_{-\mathcal{T}_{n+1}}] \leq \max_{1 \leq k \leq M} \mu_k$, $q_i^{(J-\mathcal{T}_n)} \leq \bar{q}_i$, and $\sum_{n=\lfloor x^{1/3} \rfloor}^{\infty} e^{-\mu n q_i (1-\varepsilon)} = O(1/\bar{q}_i)$. Hence, upper-bounding the preceding sum, as in (13), and using $\mathbb{P}[\mathcal{T}_0 > hx^\alpha] = o(1)$ as $x \rightarrow \infty$, we easily arrive at

$$I_{31}(x) = o\left(\frac{1}{x^{\alpha-1}}\right) \quad \text{as } x \rightarrow \infty. \quad (57)$$

In evaluating $I_{32}(x)$, we condition on the length of $\mathcal{T}_{n+1} - \mathcal{T}_n$:

$$\begin{aligned} I_{32}(x) &= \mathbb{E} \sum_{n=\lfloor x^{1/3} \rfloor}^{\infty} \int_{\mathcal{T}_n}^{\mathcal{T}_{n+1}} \hat{f}(t)1[S(t; J) > x - 1, \mathcal{T}_0 \leq hx^\alpha, \mathcal{T}_{n+1} - \mathcal{T}_n > hx^\alpha, \mathcal{A}(n)] dt \\ &\quad + \mathbb{E} \sum_{n=\lfloor x^{1/3} \rfloor}^{\infty} \int_{\mathcal{T}_n}^{\mathcal{T}_{n+1}} \hat{f}(t)1[S(t; J) > x - 1, \mathcal{T}_0 \leq hx^\alpha, \mathcal{T}_{n+1} - \mathcal{T}_n \leq hx^\alpha, \mathcal{A}(n)] dt. \end{aligned} \quad (58)$$

Thus, using (56) and $q_i^{(J_0)} \leq \bar{q}_i$, after upper-bounding and integrating the first term of the preceding equality we obtain

$$\mathbb{E} \sum_{n=\lfloor x^{1/3} \rfloor}^{\infty} \int_{\mathcal{T}_n}^{\mathcal{T}_{n+1}} \hat{f}(t)1[S(t; J) > x - 1, \mathcal{T}_0 \leq hx^\alpha, \mathcal{T}_{n+1} - \mathcal{T}_n > hx^\alpha, \mathcal{A}(n)] dt$$

$$\leq \mathbb{E} \sum_{i=1}^{\infty} \sum_{n=\lfloor x^{1/3} \rfloor}^{\infty} \bar{q}_i e^{-(1-\varepsilon)\mu n q_i} (1 - e^{-q_i^{(J-\mathcal{T}_{n+1})}(\mathcal{T}_{n+1}-\mathcal{T}_n)}) 1[\mathcal{T}_{n+1} - \mathcal{T}_n > hx^\alpha]. \tag{59}$$

Furthermore, we can upper-bound (59) by splitting the sum, using $1 - e^{-x} \leq 1$ and $1 - e^{-x} \leq x$ (both for $x \geq 0$) and $q_i^{(J-\mathcal{T}_{n+1})} \leq \bar{q}_i$ as follows:

$$\begin{aligned} & \mathbb{E} \sum_{i=1}^{\infty} \sum_{n=\lfloor x^{1/3} \rfloor}^{\infty} \bar{q}_i e^{-(1-\varepsilon)\mu n q_i} (1 - e^{-q_i^{(J-\mathcal{T}_{n+1})}(\mathcal{T}_{n+1}-\mathcal{T}_n)}) 1[\mathcal{T}_{n+1} - \mathcal{T}_n > hx^\alpha] \\ & \leq \sum_{i=1}^x \sum_{n=\lfloor x^{1/3} \rfloor}^{\infty} \bar{q}_i e^{-(1-\varepsilon)\mu n q_i} \mathbb{P}[\mathcal{T}_1 - \mathcal{T}_0 > hx^\alpha] \\ & \quad + \sum_{i=x+1}^{\infty} \bar{q}_i \sum_{n=\lfloor x^{1/3} \rfloor}^{\infty} \bar{q}_i e^{-(1-\varepsilon)\mu n q_i} \mathbb{E}[(\mathcal{T}_1 - \mathcal{T}_0) 1[\mathcal{T}_1 - \mathcal{T}_0 > hx^\alpha]]. \end{aligned}$$

Now, if in the preceding expression we use the following estimates: $\mathbb{P}[\mathcal{T}_1 - \mathcal{T}_0 > hx^\alpha] = O(1/x^{\alpha(1+\delta)})$, $\mathbb{E}[(\mathcal{T}_1 - \mathcal{T}_0) 1[\mathcal{T}_1 - \mathcal{T}_0 > hx^\alpha]] = o(1)$ as $x \rightarrow \infty$,

$$\sum_{n=\lfloor x^{1/3} \rfloor}^{\infty} \bar{q}_i e^{-(1-\varepsilon)\mu n q_i} \leq \int_{\lfloor x^{1/3} \rfloor - 1}^{\infty} \bar{q}_i e^{-(1-\varepsilon)\mu q_i y} dy \leq 1/((1 - \varepsilon)\mu \min_k \pi_k)$$

and $q_i \sim c/i^\alpha$ as $i \rightarrow \infty$, then in conjunction with (59) the first term of (58) satisfies

$$\begin{aligned} & \mathbb{E} \sum_{n=\lfloor x^{1/3} \rfloor}^{\infty} \int_{\mathcal{T}_n}^{\mathcal{T}_{n+1}} \hat{f}(t) 1[S(t; J) > x - 1, \mathcal{T}_0 \leq hx^\alpha, \mathcal{T}_{n+1} - \mathcal{T}_n > hx^\alpha, \\ & \quad \mathcal{A}(n)] dt = o\left(\frac{1}{x^{\alpha-1}}\right) \quad \text{as } x \rightarrow \infty. \end{aligned} \tag{60}$$

Therefore, replacing expression (60) for the first sum of (58) yields, as $x \rightarrow \infty$,

$$\begin{aligned} I_{32}(x) &= \mathbb{E} \sum_{n=\lfloor x^{1/3} \rfloor}^{\infty} \int_{\mathcal{T}_n}^{\mathcal{T}_{n+1}} \hat{f}(t) 1[S(\mathcal{T}_{n+1}; J) > x - 1, \mathcal{T}_0 \leq hx^\alpha, \mathcal{T}_{n+1} \\ & \quad - \mathcal{T}_n \leq hx^\alpha, \mathcal{A}(n)] dt + o\left(\frac{1}{x^{\alpha-1}}\right) \\ & \leq \mathbb{E} \sum_{n=\lfloor x^{1/3} \rfloor}^{\lfloor \varepsilon x^\alpha \rfloor} \int_{\mathcal{T}_n}^{\mathcal{T}_{n+1}} + \mathbb{E} \sum_{n=\lfloor \varepsilon x^\alpha \rfloor}^{\lfloor g_\varepsilon x^\alpha \rfloor} \int_{\mathcal{T}_n}^{\mathcal{T}_{n+1}} + \mathbb{E} \sum_{n=\lfloor g_\varepsilon x^\alpha \rfloor}^{\infty} \int_{\mathcal{T}_n}^{\mathcal{T}_{n+1}} + o\left(\frac{1}{x^{\alpha-1}}\right) \\ & \triangleq I_{32}^{(1)}(x) + I_{32}^{(2)}(x) + I_{32}^{(3)}(x) + o\left(\frac{1}{x^{\alpha-1}}\right), \end{aligned} \tag{61}$$

for some $g_\varepsilon > 0$ and $0 < \varepsilon < g_\varepsilon$ (from the later choice of g_ε it will be clear that such ε exists).

In what follows we will evaluate the expressions $I_{32}^{(k)}(x)$ from (61). Recalling the definition of $S(u, t; J)$ and using similar arguments as in (46) and (47), it is easy to show

$$\begin{aligned} & 1[S(\mathcal{T}_{n+1}; J) > x - 1, \mathcal{T}_0 \leq hx^\alpha, \mathcal{T}_{n+1} - \mathcal{T}_n \leq hx^\alpha] \\ & \leq 1[S(\mathcal{T}_0, \mathcal{T}_n; J) > (1 - 2\varepsilon)x] + 1[S(hx^\alpha; J) > \varepsilon x - (1/2)] \\ & \quad + 1[S(\mathcal{T}_n, \mathcal{T}_n + hx^\alpha; J) > \varepsilon x - (1/2)], \end{aligned} \tag{62}$$

and, therefore, replacing (56) in $I_{32}^{(1)}(x)$ and completing the integration results in

$$\begin{aligned} I_{32}^{(1)}(x) &\leq \mathbb{E} \sum_{n=\lfloor x^{1/3} \rfloor}^{\lfloor \varepsilon x^z \rfloor} \sum_{i=1}^{\infty} q_i^{(J_0)} e^{-(1-\varepsilon)nq_i\mu} \\ &\quad \times (1 - e^{-q_i^{(J-\mathcal{T}_{n+1})}(\mathcal{T}_{n+1}-\mathcal{T}_n)}) 1[S(\mathcal{T}_0, \mathcal{T}_n; J) > x(1-2\varepsilon)] \\ &\quad + 2\varepsilon x^\alpha \mathbb{P}[\bar{S}(hx^\alpha) > \varepsilon x - (1/2)], \end{aligned}$$

where h is small enough to ensure $\mathbb{E}\bar{S}(hx^\alpha) \leq (\varepsilon x - 1/2)/(1+\varepsilon)$ for large x . Next, applying Lemma 4, $\max(q_i^{(J_0)}, q_i^{(J-\mathcal{T}_{n+1})}) \leq Hq_i$, $1 - e^{-x} \leq x$ ($x \geq 0$), the fact that $(\mathcal{T}_{n+1} - \mathcal{T}_n)$ and $1[S(\mathcal{T}_0, \mathcal{T}_n; J) > (1-2\varepsilon)x]$ are conditionally independent given $J_{-\mathcal{T}_n}$ and (36) renders, as $x \rightarrow \infty$,

$$\begin{aligned} I_{32}^{(1)}(x) &\leq H \sum_{n=\lfloor x^{1/3} \rfloor}^{\lfloor \varepsilon x^z \rfloor} \sum_{i=1}^{\infty} q_i^2 e^{-(1-\varepsilon)n\mu q_i} \\ &\quad \times \mathbb{E}[\mathbb{E}[\mathcal{T}_{n+1} - \mathcal{T}_n | J_{-\mathcal{T}_n}] \mathbb{P}[S(\mathcal{T}_0, \mathcal{T}_n; J) > x(1-2\varepsilon) | J_{-\mathcal{T}_n}]] \\ &\quad + o\left(\frac{1}{x^{\alpha-1}}\right) \\ &\leq H \sum_{n=\lfloor x^{1/3} \rfloor}^{\lfloor \varepsilon x^z \rfloor} \sum_{i=1}^{\infty} q_i^2 e^{-(1-\varepsilon)n\mu q_i} \mathbb{P}[\bar{S}(\mathcal{T}_n - \mathcal{T}_0) > x(1-2\varepsilon)] \\ &\quad + o\left(\frac{1}{x^{\alpha-1}}\right). \end{aligned}$$

Now, by using the argument as in inequality (48) and Lemmas 2 and 7, we derive, as $x \rightarrow \infty$,

$$I_{32}^{(1)}(x) \leq \frac{H}{x^{\alpha(1+\delta)}} \sum_{n=\lfloor x^{1/3} \rfloor}^{\lfloor \varepsilon x^z \rfloor} \frac{1}{n^{1-\frac{1}{z}}} + o\left(\frac{1}{x^{\alpha-1}}\right) = o\left(\frac{1}{x^{\alpha-1}}\right), \quad (63)$$

when ε is smaller than sh with s as in Lemma 7.

Now, we estimate $I_{32}^{(2)}(x)$ by replacing (56) in $I_{32}^{(2)}(x)$, completing the integration and applying similar arguments as in (62) and, therefore, as $x \rightarrow \infty$,

$$\begin{aligned} I_{32}^{(2)}(x) &\leq \mathbb{E} \sum_{n=\lfloor \varepsilon x^z \rfloor}^{\lfloor g_\varepsilon x^z \rfloor} \sum_{i=1}^{\infty} q_i^{(J_0)} e^{-(1-\varepsilon)nq_i\mu} \\ &\quad \times (1 - e^{-q_i^{(J-\mathcal{T}_{n+1})}(\mathcal{T}_{n+1}-\mathcal{T}_n)}) 1[S(\mathcal{T}_0, \mathcal{T}_n; J) > (1-2\varepsilon)x] + o\left(\frac{1}{x^{\alpha-1}}\right). \end{aligned}$$

Then, by using $\max(q_i^{(J_0)}, q_i^{(J-\mathcal{T}_{n+1})}) \leq Hq_i$, $1 - e^{-x} \leq x$ ($x \geq 0$), (36), the fact that $(\mathcal{T}_{n+1} - \mathcal{T}_n)$ and $1[S(\mathcal{T}_0, \mathcal{T}_n; J) > (1-2\varepsilon)x]$ are conditionally independent given $J_{-\mathcal{T}_n}$, we obtain, as $x \rightarrow \infty$,

$$\begin{aligned} I_{32}^{(2)}(x) &\leq H \sum_{n=\lfloor \varepsilon x^z \rfloor}^{\lfloor g_\varepsilon x^z \rfloor} \sum_{i=1}^{\infty} q_i^2 e^{-(1-\varepsilon)nq_i\mu} \\ &\quad \times \mathbb{E} \left[\mathbb{E}[\mathcal{T}_{n+1} - \mathcal{T}_n | J_{-\mathcal{T}_n}] \mathbb{P} \left[S(\mathcal{T}_0, \mathcal{T}_n; J) > x(1-2\varepsilon) \mid J_{-\mathcal{T}_n} \right] \right] \\ &\quad + o\left(\frac{1}{x^{\alpha-1}}\right) \end{aligned}$$

$$\leq H \sum_{n=\lfloor \varepsilon x^\alpha \rfloor}^{\lfloor g_\varepsilon x^\alpha \rfloor} \sum_{i=1}^{\infty} q_i^2 e^{-(1-\varepsilon)nq_i \mu} \times \mathbb{P} [S(\mathcal{T}_0, \mathcal{T}_{\lfloor g_\varepsilon x^\alpha \rfloor}; J) > x(1 - 2\varepsilon)] + o\left(\frac{1}{x^{\alpha-1}}\right).$$

Define

$$\mathcal{B}(x) \triangleq \bigcap_{1 \leq k \leq M} \{\tau_k(\mathcal{T}_0, \lfloor g_\varepsilon x^\alpha \rfloor) \leq (1 + \varepsilon)\mu_k \nu_k g_\varepsilon x^\alpha\}.$$

Then, as $x \rightarrow \infty$,

$$\begin{aligned} I_{32}^{(2)}(x) &\leq H \sum_{n=\lfloor \varepsilon x^\alpha \rfloor}^{\lfloor g_\varepsilon x^\alpha \rfloor} \sum_{i=1}^{\infty} q_i^2 e^{-(1-\varepsilon)\mu n q_i} \mathbb{P} [S(\mathcal{T}_0, \mathcal{T}_{\lfloor g_\varepsilon x^\alpha \rfloor}; J) > x(1 - 2\varepsilon), \mathcal{B}(x)] \\ &\quad + H \sum_{n=\lfloor \varepsilon x^\alpha \rfloor}^{\lfloor g_\varepsilon x^\alpha \rfloor} \sum_{i=1}^{\infty} q_i^2 e^{-(1-\varepsilon)\mu n q_i} \mathbb{P}[\mathcal{B}^c(x)] + o\left(\frac{1}{x^{\alpha-1}}\right). \end{aligned} \tag{64}$$

Now, we will evaluate the two sums from the preceding inequality. Due to the weak law of large numbers, $\mathbb{P}[\tau_k(\mathcal{T}_0, \lfloor g_\varepsilon x^\alpha \rfloor) > (1 + \varepsilon)\mu_k \nu_k g_\varepsilon x^\alpha] \rightarrow 0$, implying $\mathbb{P}[\mathcal{B}^c(x)] \rightarrow 0$ as $x \rightarrow \infty$, which, in conjunction with Lemma 2, yields as $x \rightarrow \infty$

$$H \sum_{n=\lfloor \varepsilon x^\alpha \rfloor}^{\lfloor g_\varepsilon x^\alpha \rfloor} \sum_{i=1}^{\infty} q_i^2 e^{-(1-\varepsilon)\mu n q_i} \mathbb{P}[\mathcal{B}^c(x)] = o(1) \sum_{n=\lfloor \varepsilon x^\alpha \rfloor}^{\lfloor g_\varepsilon x^\alpha \rfloor} n^{-2+\frac{1}{\alpha}} = o\left(\frac{1}{x^{\alpha-1}}\right). \tag{65}$$

Next, we estimate the probability $\mathbb{P}[S(\mathcal{T}_0, \mathcal{T}_{\lfloor g_\varepsilon x^\alpha \rfloor}; J) > (1 - 2\varepsilon)x, \mathcal{B}(x)]$. Let $B_i(u, t; J)$, $0 < u < t$, be a random variable indicating whether item i is requested in $[-t, -u]$. Define $S^*(x) = \sum_{i=1}^{\infty} B_i^*(x)$, where $\{B_i^*(x), i \geq 1\}$ is a sequence of independent Bernoulli random variables with $\mathbb{P}[B_i^*(x) = 1] = 1 - e^{-(1+\varepsilon)\sum_{k=1}^M q_i^{(k)} \mu \pi_k g_\varepsilon x^\alpha}$; similarly as before, $S^*(x)$ is constructed non-decreasing in x . Then, for every $\omega \in \mathcal{B}(x)$,

$$\begin{aligned} \mathbb{P}_{\sigma_{\mathcal{T}_{\lfloor g_\varepsilon x^\alpha \rfloor}}} [B_i(\mathcal{T}_0, \mathcal{T}_{\lfloor g_\varepsilon x^\alpha \rfloor}; J) = 1] &= 1 - e^{-\sum_{k=1}^M q_i^{(k)} \tau_k(\mathcal{T}_0, \lfloor g_\varepsilon x^\alpha \rfloor)} \\ &\leq \mathbb{P}[B_i^*(x) = 1]. \end{aligned}$$

Therefore, by stochastic dominance, for every $\omega \in \mathcal{B}(x)$

$$\mathbb{P}_{\sigma_{\mathcal{T}_{\lfloor g_\varepsilon x^\alpha \rfloor}}} [S(\mathcal{T}_0, \mathcal{T}_{\lfloor g_\varepsilon x^\alpha \rfloor}; J) > (1 - 2\varepsilon)x] \leq \mathbb{P} [S^*(x) > (1 - 2\varepsilon)x]. \tag{66}$$

If we select

$$g_\varepsilon = \frac{(1 - 4\varepsilon)^\alpha}{(1 + \varepsilon)c\mu\Gamma\left[1 - \frac{1}{\alpha}\right]^\alpha},$$

it is easy to check, using Lemma 3, that for all x large enough

$$\mathbb{E}S^*(x) = \sum_{i=1}^{\infty} (1 - e^{-(1+\varepsilon)\sum_{k=1}^M \pi_k \mu g_\varepsilon x^\alpha q_i^{(k)}}) < (1 - 3\varepsilon)x.$$

This inequality, (66), and Lemma 4 imply, after setting $\varepsilon = \varepsilon/(1 - 3\varepsilon)$, for all x large enough,

$$\mathbb{P} [S(\mathcal{T}_0, \mathcal{T}_{\lfloor g_\varepsilon x^\alpha \rfloor}; J) > (1 - 2\varepsilon)x, \mathcal{B}(x)] \leq \mathbb{P} [S^*(x) > (1 - 2\varepsilon)x] \leq H e^{-\theta_\varepsilon x},$$

for some positive constant θ_ε . Therefore, by using Lemma 2, the upper bound on the first expression in (64) is

$$\sum_{n=\lfloor \varepsilon x^\alpha \rfloor}^{\lfloor g_\varepsilon x^\alpha \rfloor} \sum_{i=1}^{\infty} q_i^2 e^{-(1-\varepsilon)\mu n q_i} \mathbb{P} [S^*(x) > (1 - 2\varepsilon)x] = o\left(\frac{1}{x^{\alpha-1}}\right) \quad \text{as } x \rightarrow \infty,$$

which in conjunction with (65) implies

$$I_{32}^{(2)}(x) = o\left(\frac{1}{x^{\alpha-1}}\right) \quad \text{as } x \rightarrow \infty. \tag{67}$$

Finally, after replacing (56) in $I_{32}^{(3)}(x)$, computing the integral, applying $1 - e^{-x} \leq x$, $x \geq 0$ and using double conditioning, we obtain for any integer $\chi \geq 1$

$$\begin{aligned} I_{32}^{(3)}(x) &\leq \mathbb{E} \sum_{n=\lfloor g_\varepsilon x^\alpha \rfloor}^{\infty} \sum_{i=1}^{\infty} q_i^{(J_0)} q_i^{(J-\mathcal{T}_{n+1})} \mu_{J-\mathcal{T}_{n+1}} e^{-q_i \mu n (1-\varepsilon)} \\ &\leq \mathbb{E} \sum_{j=0}^{\infty} \sum_{i=1}^{\infty} \mathbb{E}[q_i^{(J_0)} | J-\mathcal{T}_{\lfloor g_\varepsilon x^\alpha \rfloor + j\chi}] e^{-(1-\varepsilon)\mu(\lfloor g_\varepsilon x^\alpha \rfloor + j\chi)q_i} \\ &\quad \sum_{n=\lfloor g_\varepsilon x^\alpha \rfloor + j\chi}^{\lfloor g_\varepsilon x^\alpha \rfloor + (j+1)\chi} \mathbb{E}[q_i^{(J-\mathcal{T}_{n+1})} \mu_{J-\mathcal{T}_{n+1}} | J-\mathcal{T}_{\lfloor g_\varepsilon x^\alpha \rfloor + j\chi}]; \end{aligned} \tag{68}$$

in the last inequality we split the first sum, apply the conditional independence of J_0 and $\{J-\mathcal{T}_n, \lfloor g_\varepsilon x^\alpha \rfloor + j\chi \leq n \leq \lfloor g_\varepsilon x^\alpha \rfloor + (j+1)\chi\}$ given $J-\mathcal{T}_{\lfloor g_\varepsilon x^\alpha \rfloor + j\chi}$ and use the monotonicity of e^{-x} . Now, by ergodicity of the Markov chain $\{J-\mathcal{T}_n\}$ (see Theorem 2.26 on p. 160 of [7]) and finiteness of its state space, for χ large enough, all $j \geq 0$ and all $i \geq 1$

$$\begin{aligned} &\sum_{n=\lfloor g_\varepsilon x^\alpha \rfloor + j\chi}^{\lfloor g_\varepsilon x^\alpha \rfloor + (j+1)\chi} \mathbb{E}[q_i^{(J-\mathcal{T}_{n+1})} \mu_{J-\mathcal{T}_{n+1}} | J-\mathcal{T}_{\lfloor g_\varepsilon x^\alpha \rfloor + j\chi} = l] \\ &= \sum_{k=1}^M q_i^{(k)} \mu_k \sum_{n=0}^{\chi} \mathbb{E}[J-\mathcal{T}_{n+1} = k | J-\mathcal{T}_0 = l] \leq (1 + \varepsilon)\chi q_i \mu. \end{aligned}$$

Therefore, after summing over all j and taking expectation, we derive

$$\begin{aligned} I_{32}^{(3)}(x) &\leq \sum_{i=1}^{\infty} q_i^2 (1 + \varepsilon) \mu e^{-q_i \mu (1-\varepsilon) \lfloor g_\varepsilon x^\alpha \rfloor} \frac{\chi}{1 - e^{-\chi \mu q_i (1-\varepsilon)}} \\ &= \int_{\lfloor g_\varepsilon x^\alpha \rfloor}^{\infty} \sum_{i=1}^{\infty} q_i^2 (1 + \varepsilon) \mu e^{-q_i \mu (1-\varepsilon)t} \frac{q_i \mu \chi (1 - \varepsilon)}{1 - e^{-\chi \mu q_i (1-\varepsilon)}} dt. \end{aligned}$$

Now, since $x/(1 - e^{-x}) \rightarrow 1$ as $x \rightarrow 0$, we can choose i_0 such that $q_i \mu \chi (1 - \varepsilon) / (1 - e^{-\chi \mu q_i (1-\varepsilon)}) \leq 1 + \varepsilon$ for all $i \geq i_0$; thus, we can further upper bound $I_{32}^{(3)}(x)$ as

$$I_{32}^{(3)}(x) \leq H i_0 e^{-h q_{i_0} x^\alpha} + \int_{\lfloor g_\varepsilon x^\alpha \rfloor}^{\infty} \sum_{i=1}^{\infty} q_i^2 (1 + \varepsilon)^2 \mu e^{-q_i \mu (1-\varepsilon)t} dt. \tag{69}$$

At last, since the first term in the preceding expression equals $o(1/x^{\alpha-1})$ as $x \rightarrow \infty$, using Lemma 2 and the expression for g_ε , we compute

$$\limsup_{x \rightarrow \infty} \frac{I_{32}^{(3)}(x)}{\mathbb{P}[R > x]} \leq K(\alpha) \frac{(1 + \varepsilon)^{3-\frac{1}{\alpha}} (1 - \varepsilon)^{-2+\frac{1}{\alpha}}}{(1 - 4\varepsilon)^{\alpha-1}}.$$

By passing $\varepsilon \rightarrow 0$ in the last inequality and then replacing it together with estimates (67) and (63) in (61), we derive

$$\limsup_{x \rightarrow \infty} \frac{I_{32}(x)}{\mathbb{P}[R > x]} \leq K(\alpha). \tag{70}$$

Finally, (70), (57), (55), (40), (49), and Proposition 2 conclude the proof. \square

Acknowledgements

We are very grateful to the anonymous reviewer for the detailed proofreading and valuable suggestions.

Appendix A.

Proof of Proposition 1. By Theorem 1, for any finite N , the stationary search cost is given by

$$\mathbb{P}[C^N > x] = \mathbb{E} \int_0^\infty \sum_{i=1}^N q_i^{(J_0)} q_i^{(J_{-t})} e^{-\hat{q}_i t} \mathbb{P}_{\sigma_t}[S_{i,N}(t; J) > x - 1] dt. \tag{71}$$

Clearly, the term under the integral in the preceding equation converges to the corresponding term in (10) as $N \rightarrow \infty$. Hence, in order to apply the Dominated Convergence Theorem, it remains to show that, uniformly in N , the integrand in (71) is bounded by an integrable function. To this end, let $\hat{q}_{i,N}$, $i \geq 1$, correspond to the empirical distribution defined in (8) with $q_i^{(k)}$ replaced by $q_{i,N}^{(k)}$. Then, since $\frac{1}{\sum_{i=1}^N q_i^{(k)}} \searrow 1$ as $N \rightarrow \infty$, there exists $N_0 \geq 1$, such that for all $N \geq N_0$, $1 \leq i \leq N$, and $1 \leq k \leq M$,

$$q_i^{(k)} \leq q_{i,N}^{(k)} \leq 2q_i^{(k)}.$$

Thus, the function under the integral in (71) is almost surely bounded by

$$4 \sum_{i=1}^\infty q_i^{(J_0)} q_i^{(J_{-t})} e^{-\hat{q}_i t}. \tag{72}$$

Since $-d(e^{-\hat{q}_i t}) = e^{-\hat{q}_i t} d(\sum_{k=1}^M q_i^{(k)} \int_{-t}^0 1[J_u = k] du) = e^{-\hat{q}_i t} q_i^{(J_{-t})} dt$, and, due to ergodicity, $\hat{q}_i t = \sum_{k=1}^M q_i^{(k)} \int_{-t}^0 1[J_u = k] du \rightarrow \infty$ as $t \rightarrow \infty$ a.s., we conclude that the function in (72) is integrable, i.e.,

$$\mathbb{E} \int_0^\infty 4 \sum_{i=1}^\infty q_i^{(J_0)} q_i^{(J_{-t})} e^{-\hat{q}_i t} dt = -4 \mathbb{E} \int_0^\infty \sum_{i=1}^\infty q_i^{(J_0)} d(e^{-\hat{q}_i t}) = 4. \quad \square$$

Proof of Lemma 4. Let $m_i \triangleq \mathbb{E}B_i$, $i \geq 1$. For an arbitrary $0 < \varepsilon < 1$

$$\mathbb{P}[|S - m| > m\varepsilon] = \mathbb{P}[S > m(1 + \varepsilon)] + \mathbb{P}[-S > -m(1 - \varepsilon)]. \tag{73}$$

Now, using Markov's inequality, for any $\theta > 0$ we obtain

$$\mathbb{P}[S > m(1 + \varepsilon)] = \mathbb{P}[e^{\theta S} > e^{\theta m(1 + \varepsilon)}] \leq \frac{\mathbb{E}e^{\theta S}}{e^{\theta m(1 + \varepsilon)}}. \quad (74)$$

Since $\{B_i, i \geq 1\}$ are independent Bernoulli random variables,

$$\mathbb{E}e^{\theta S} = \prod_{i=1}^{\infty} \mathbb{E}e^{\theta B_i} = \prod_{i=1}^{\infty} (e^{\theta m_i} + (1 - m_i)) \leq \prod_{i=1}^{\infty} e^{m_i(e^{\theta} - 1)} = e^{m(e^{\theta} - 1)},$$

and, therefore, using (74), we derive

$$\mathbb{P}[S > m(1 + \varepsilon)] \leq e^{m(e^{\theta} - 1 - \theta(1 + \varepsilon))}.$$

We can choose $\theta > 0$ such that $e^{\theta} - 1 - \theta(1 + \varepsilon) = -\theta_{\varepsilon}^{(1)} < 0$. Similarly, the second expression of (73) is bounded by $e^{-\theta_{\varepsilon}^{(2)} m}$ for some $\theta_{\varepsilon}^{(2)} > 0$. By taking $\theta_{\varepsilon} = \min(\theta_{\varepsilon}^{(1)}, \theta_{\varepsilon}^{(2)})$, we complete the proof. \square
