February 10, 2009

- 1 Motivation: Why & how
- 2 Auditory physiology
- 3 Psychophysics: Detection & discrimination
- 4 Pitch perception
- 5 Speech perception
- 6 Auditory organization & Scene analysis

# Outline

- 1 Motivation: Why & how
- 2 Auditory physiology
- 3 Psychophysics: Detection & discrimination
- 4 Pitch perception
- 5 Speech perception
- 6 Auditory organization & Scene analysis

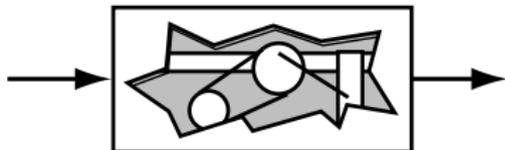

# Why study perception?

- Perception is messy: can we avoid it?  
No!
- Audition provides the 'ground truth' in audio
  - ▶ what is relevant and irrelevant
  - ▶ subjective importance of distortion (coding etc.)
  - ▶ (there could be other information in sound. . .)
- Some sounds are 'designed' for audition
  - ▶ co-evolution of speech and hearing
- The auditory system is very successful
  - ▶ we would do extremely well to duplicate it
- We are now able to model complex systems
  - ▶ faster computers, bigger memories

# How to study perception?

Three different approaches:

- Analyze the **example**: **physiology**

- ▶ dissection & nerve recordings

- **Black box** input/output: **psychophysics**

- ▶ fit simple models of simple functions

- **Information processing** models

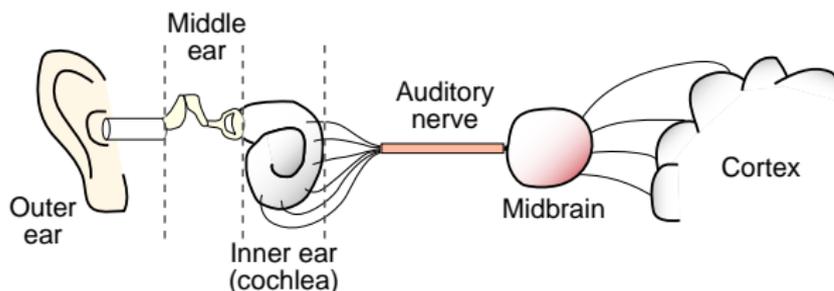

- ▶ investigate and model complex functions

*e.g.* scene analysis, speech perception

# Outline

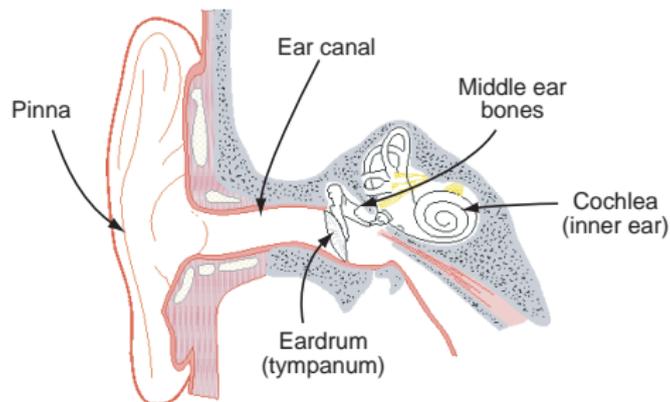

- 1 Motivation: Why & how
- 2 Auditory physiology**
- 3 Psychophysics: Detection & discrimination
- 4 Pitch perception
- 5 Speech perception
- 6 Auditory organization & Scene analysis

- Processing chain from air to brain:

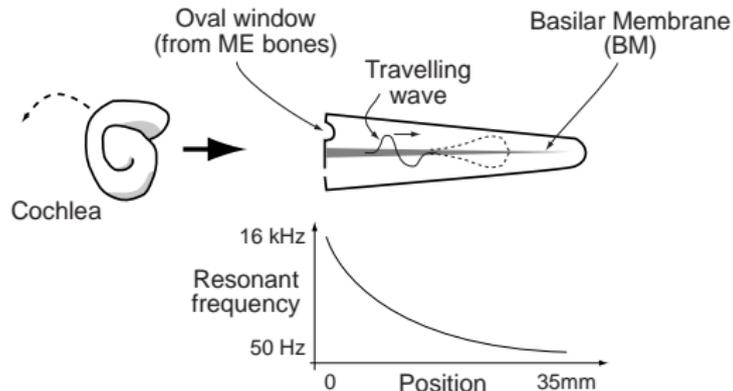

- Study via:
  - ▶ anatomy
  - ▶ nerve recordings
- Signals flow in **both directions**

## Outer & middle ear

- Pinna 'horn'
  - ▶ complex reflections give spatial (elevation) cues
- Ear canal
  - ▶ **acoustic tube**
- Middle ear
  - ▶ bones provide impedance matching

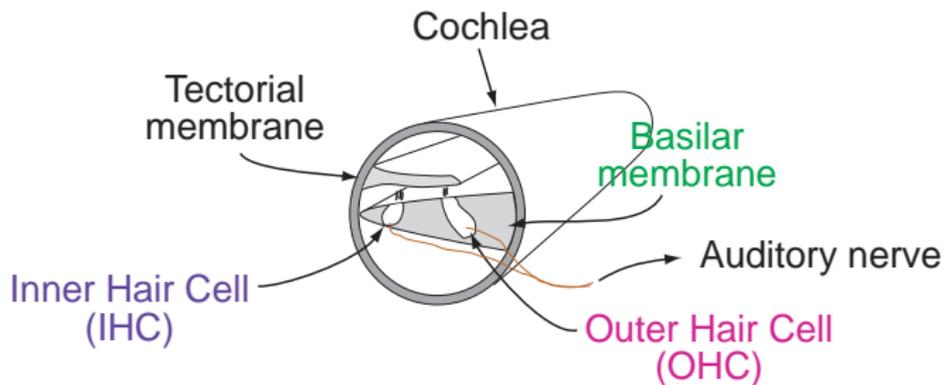

# Inner ear: Cochlea

- Mechanical input from middle ear starts **traveling wave** moving down Basilar membrane
- Varying stiffness and mass of BM results in continuous variation of **resonant frequency**
- At resonance, traveling wave energy is dissipated in **BM vibration**
  - ▶ Frequency (Fourier) analysis

# Cochlea hair cells

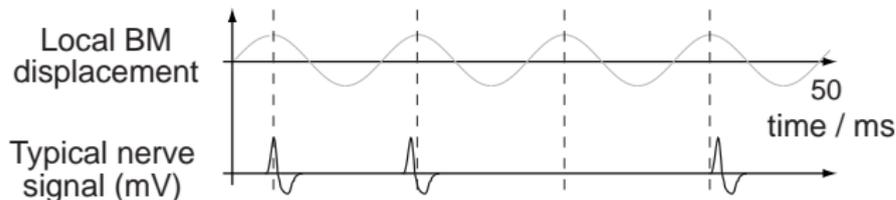

- Ear converts sound to BM motion
  - ▶ each point on BM corresponds to a frequency

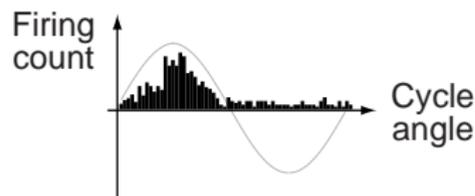

- Hair cells on BM convert motion into nerve impulses (firings)
- Inner Hair Cells detect motion
- **Outer Hair Cells?** Variable damping?

# Inner Hair Cells

- IHCs convert BM vibration into **nerve firings**
- Human ear has  $\sim 3500$  IHCs
  - ▶ each IHC has  $\sim 7$  connections to Auditory Nerve
- Each nerve **fires** (sometimes) near peak displacement

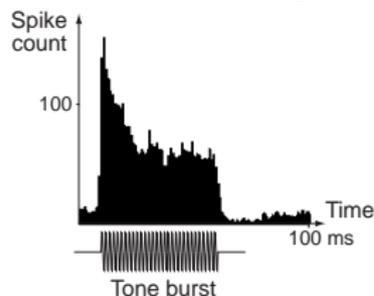

- Histogram to get firing probability

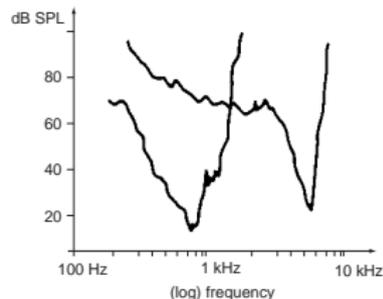

# Auditory nerve (AN) signals

## Single nerve measurements

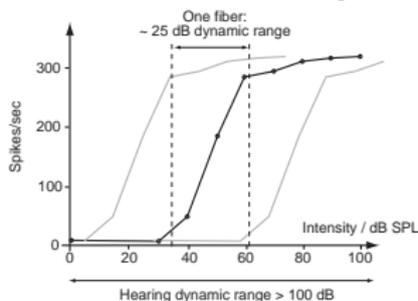

### Tone burst histogram

### Frequency threshold

### Rate vs intensity

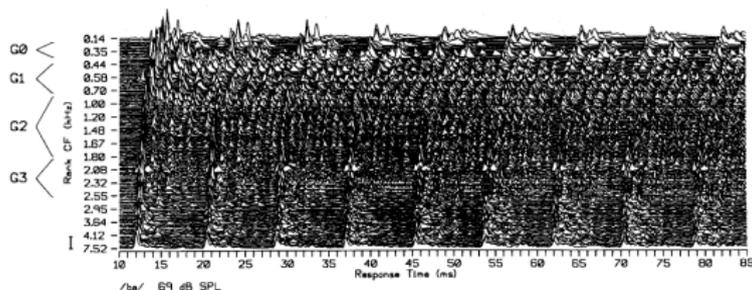

Hard to measure: probe living ANs?

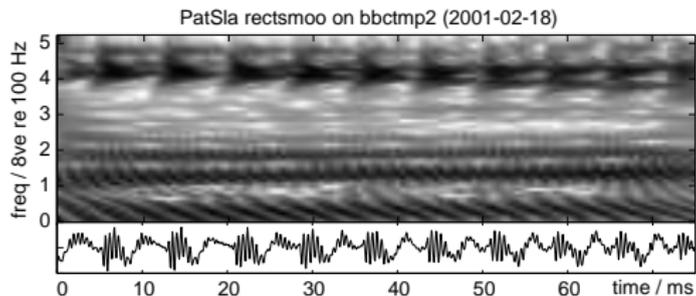

# AN population response

All the information the brain has about sound

- average rate & spike timings on 30,000 fibers

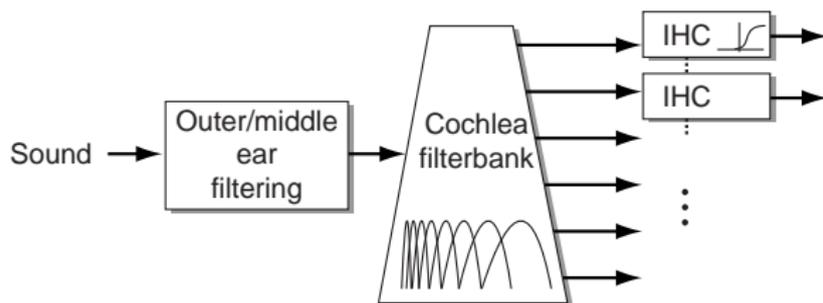

Not unlike a (constant-Q) spectrogram

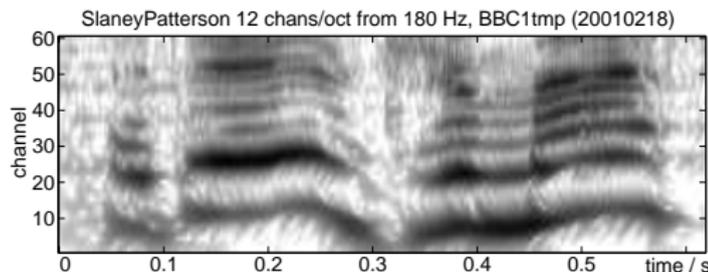

# Periphery models

- Modeled aspects
  - ▶ outer / middle ear
  - ▶ hair cell transduction
  - ▶ cochlea filtering
  - ▶ efferent feedback?

Results: 'neurogram' / 'cochleagram'

# Outline

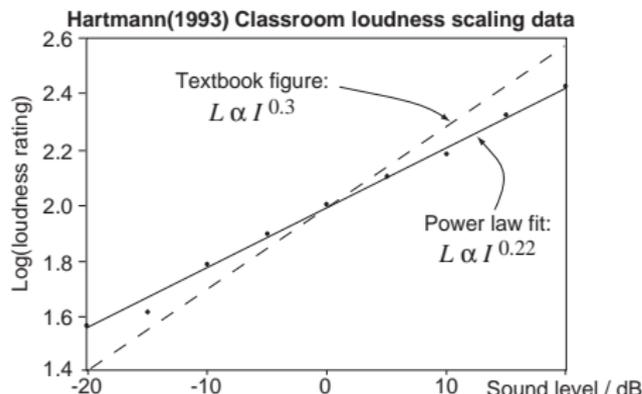

- 1 Motivation: Why & how
- 2 Auditory physiology
- 3 Psychophysics: Detection & discrimination**
- 4 Pitch perception
- 5 Speech perception
- 6 Auditory organization & Scene analysis

# Psychophysics

- **Physiology** looks at the implementation  
Psychology looks at the function/behavior
- Analyze audition as **signal detection**:  $p(\theta | x)$ 
  - ▶ psychological tests reflect internal decisions
  - ▶ assume optimal decision process
  - ▶ infer nature of internal representations, noise, ...→ lower bounds on more complex functions
- Different aspects to measure
  - ▶ time, frequency, intensity
  - ▶ tones, complexes, noise
  - ▶ binaural
  - ▶ pitch, detuning

# Basic psychophysics

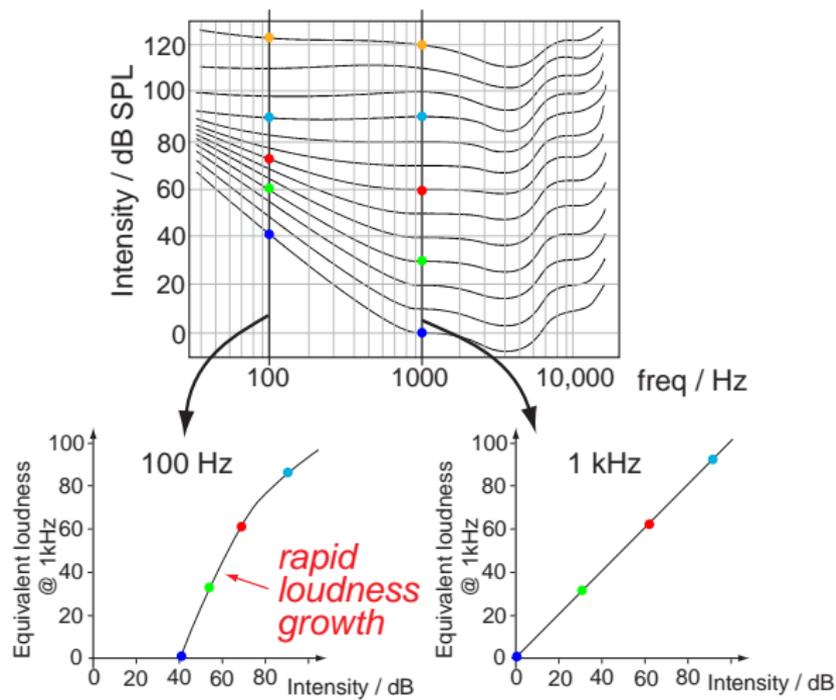

- Relate **physical** and perceptual variables  
e.g. **intensity**  $\rightarrow$  loudness  
**frequency**  $\rightarrow$  pitch
- Methodology: subject tests
  - ▶ just noticeable difference (JND)
  - ▶ magnitude scaling e.g. “adjust to twice as loud”
- Results for **Intensity** vs Loudness:  
**Weber's law**  $\Delta I \propto I \Rightarrow \log(L) = k \log(I)$

$$\begin{aligned}\log_2(L) &= 0.3 \log_2(I) \\ &= 0.3 \frac{\log_{10} I}{\log_{10} 2} \\ &= \frac{0.3 \text{ dB}}{\log_{10} 2} \frac{1}{10} \\ &= \text{dB}/10\end{aligned}$$

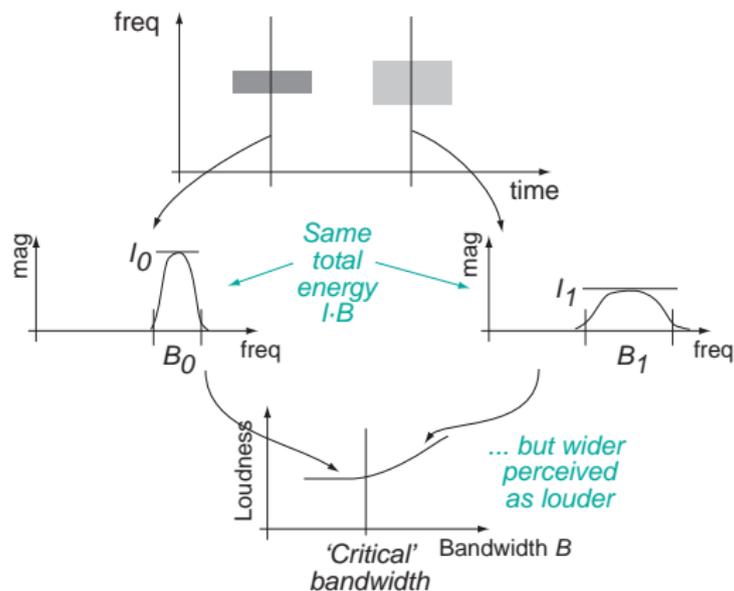

# Loudness as a function of frequency

## Fletcher-Munsen equal-loudness curves

## Loudness as a function of bandwidth

- Same total energy, different distribution  
*e.g.* 2 channels at  $-6$  dB (not  $-10$  dB)

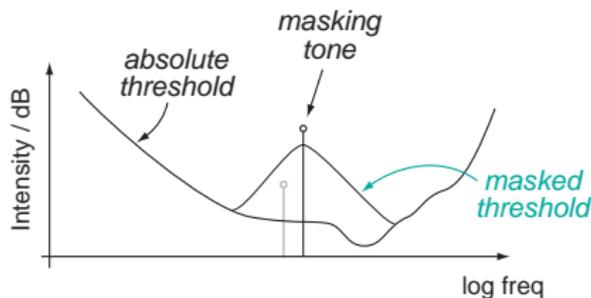

- Critical bands: independent frequency channels
  - ▶  $\sim 25$  total (4-6 / octave)

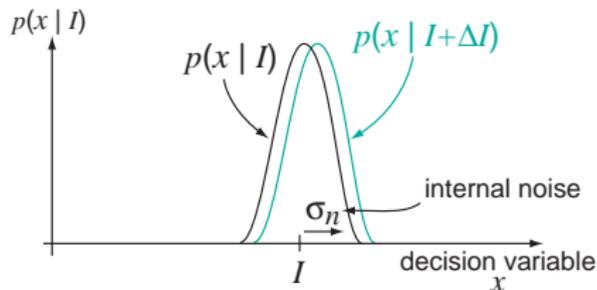

# Simultaneous masking

A louder tone can 'mask' the perception of a second tone nearby in frequency:

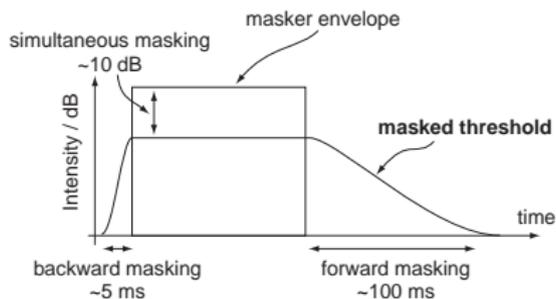

Suggests an 'internal noise' model:

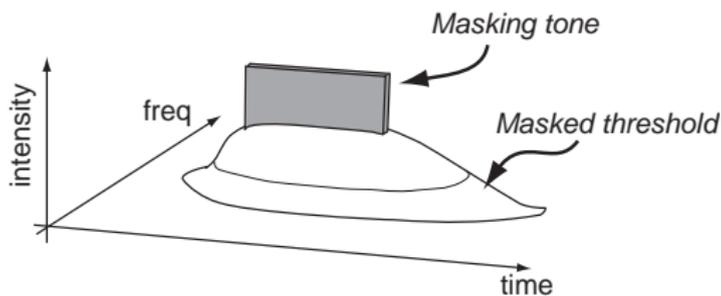

# Sequential masking

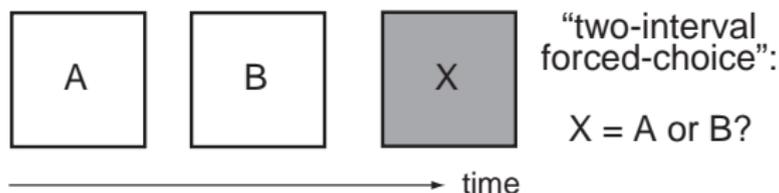

Backward/forward in time:

→ Time-frequency masking 'skirt':

## What we do and don't hear

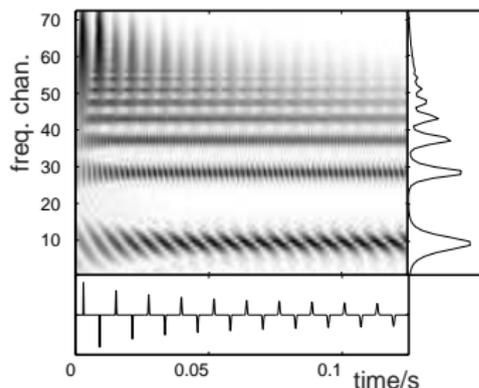

- Timing: 2 ms attack resolution, 20 ms discrimination
  - ▶ but: spectral splatter
- Tuning:  $\sim 1\%$  discrimination
  - ▶ but: beats
- Spectrum: profile changes, formants
  - ▶ variables time-frequency resolution
- Harmonic phase?
- Noisy signals & texture
- (Trace vs categorical memory)

# Outline

- 1 Motivation: Why & how
- 2 Auditory physiology
- 3 Psychophysics: Detection & discrimination
- 4 Pitch perception**
- 5 Speech perception
- 6 Auditory organization & Scene analysis

# Pitch perception: a classic argument in psychophysics

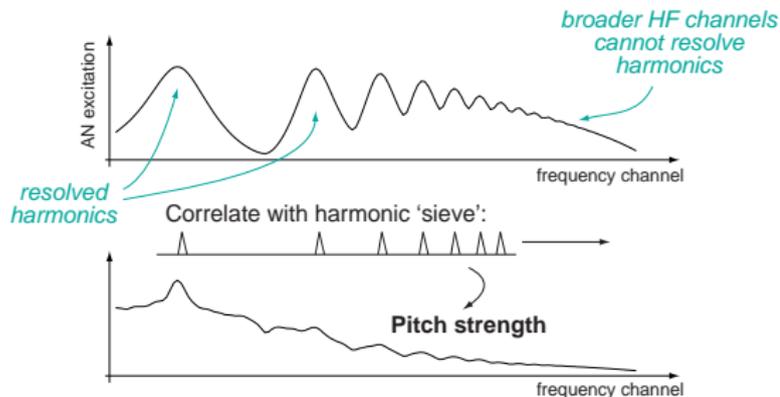

- Harmonic complexes are a pattern on AN

- ▶ but give a *fused* percept (ecological)
- What determines the pitch percept?
  - ▶ *not* the fundamental
- How is it computed?  
Two competing models: **place** and **time**

# Place model of pitch

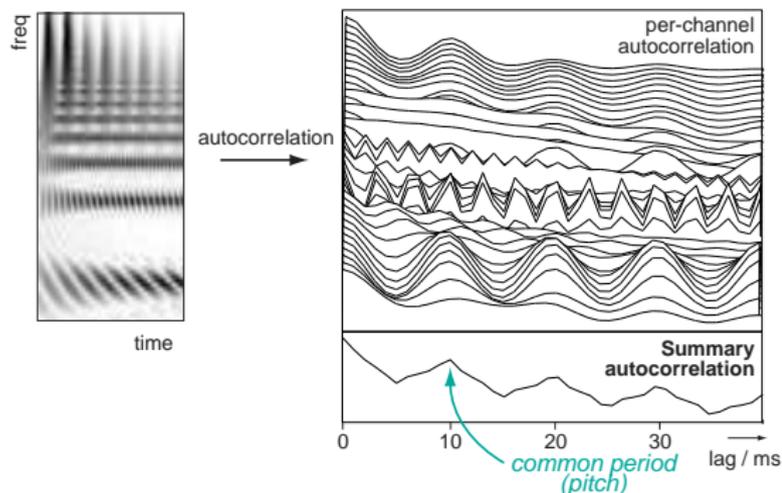

- AN excitation pattern shows individual peaks
- 'Pattern matching' method to find pitch

- Support: Low harmonics are very important
- But: Flat-spectrum noise can carry pitch

## Time model of pitch

- Timing information is preserved in AN down to  $\sim 1$  ms scale
- Extract periodicity by e.g. autocorrelation and combine across frequency channels

- But: HF gives weak pitch (in practice)

## Alternate & competing cues

- Pitch perception could rely on various cues
    - ▶ average excitation pattern
    - ▶ summary autocorrelation
    - ▶ more complex pattern matching
  - Relying on just one cue is **brittle**
    - ▶ e.g. missing fundamental
- Perceptual system appears to use a flexible, **opportunistic** combination
- Optimal detector justification?

$$\begin{aligned}\operatorname{argmax}_{\theta} p(\theta | \mathbf{x}) &= \operatorname{argmax}_{\theta} p(\mathbf{x} | \theta)p(\theta) \\ &= \operatorname{argmax}_{\theta} p(x_1 | \theta)p(x_2 | \theta)p(\theta)\end{aligned}$$

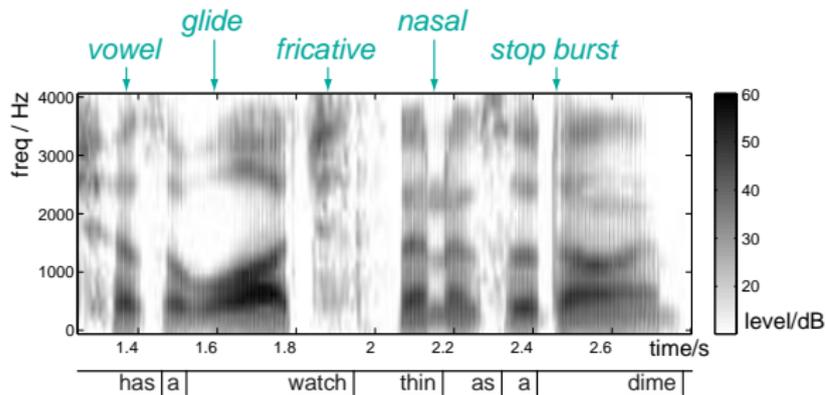

- ▶ if  $x_1$  and  $x_2$  are **conditionally independent**

# Outline

- 1 Motivation: Why & how
- 2 Auditory physiology
- 3 Psychophysics: Detection & discrimination
- 4 Pitch perception
- 5 Speech perception**
- 6 Auditory organization & Scene analysis

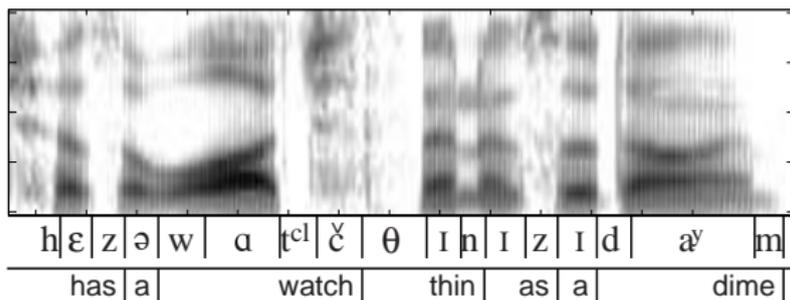

# Speech perception

- Highly specialized function
  - ▶ subsequent to source organization?
    - ... but also can interact
- Kinds of speech sounds

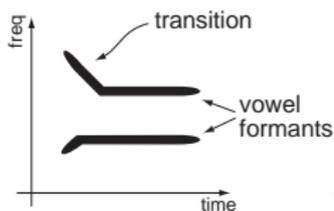

# Cues to phoneme perception

Linguists describe speech with **phonemes**

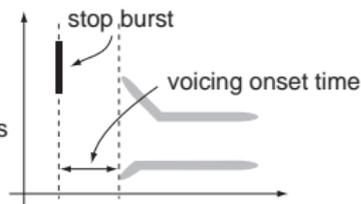

Acoustic-phoneticians describe phonemes by

- **formants & transitions**

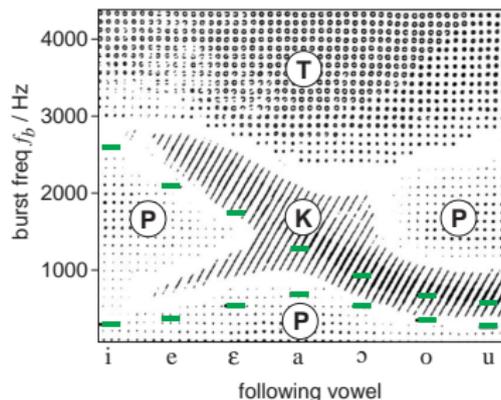

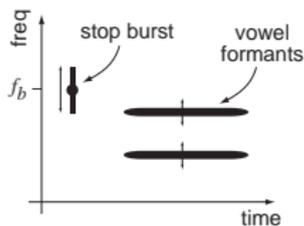

- **bursts & onset times**

# Categorical perception

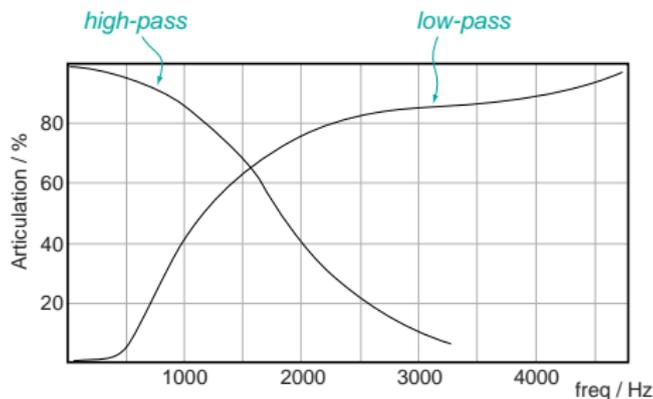

- (Some) speech sounds perceived **categorically** rather than analogically
  - ▶ e.g. stop-burst and timing:

- ▶ tokens within category are hard to distinguish
- ▶ category boundaries are very sharp
- Categories are learned for native tongue
  - ▶ “merry” / “Mary” / “marry”

# Where is the information in speech?

'Articulation' of high/low-pass filtered speech:

- sums to more than 1...

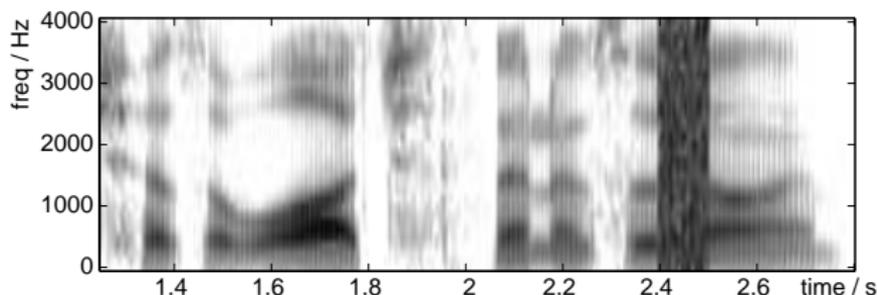

Speech message is highly redundant

*e.g.* constraints of language, context

→ listeners can understand with **very few** cues

# Top-down influences: Phonemic restoration (Warren, 1970)

What if a noise burst obscures speech?

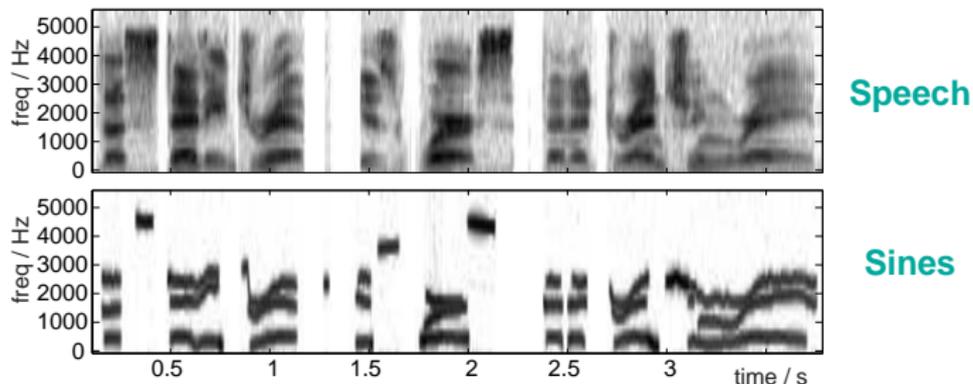

- auditory system 'restores' the missing phoneme
  - ... based on **semantic** content
  - ... even in **retrospect**

Subjects are typically unaware of which sounds are restored

## A predisposition for speech: Sinewave replicas

Replace each formant with a **single sinusoid** (Remez et al., 1981)

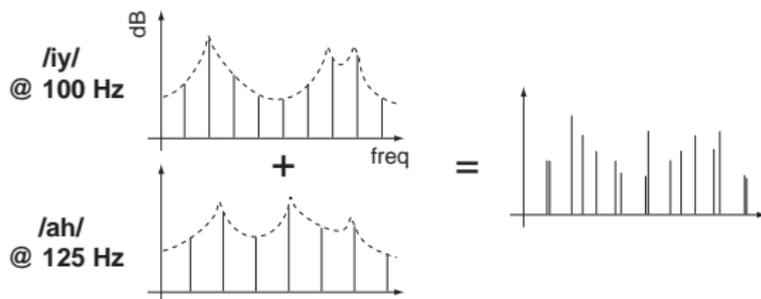

- speech is (somewhat) intelligible 
- people hear both whistles and speech (“duplex”)
- processed as speech despite un-speech-like

What does it take to be speech?

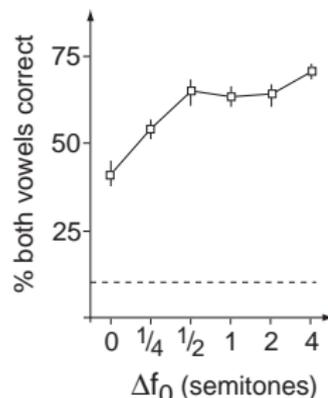

# Simultaneous vowels

Mix synthetic vowels with different  $f_0$ s

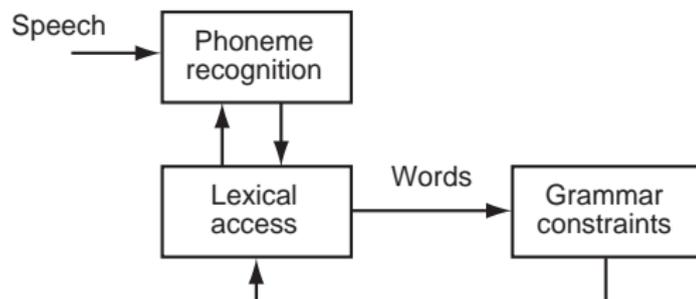

Pitch difference helps  
(though not necessarily)

DV identification vs.  $\Delta f_0$  (200ms)  
(Culling & Darwin 1993)

# Computational models of speech perception

- Various theoretical-practical models of speech comprehension  
*e.g.*

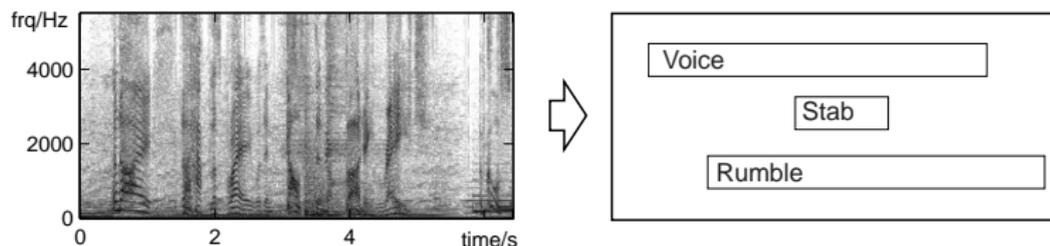

- Open questions:
  - ▶ mechanism of phoneme classification
  - ▶ mechanism of lexical recall
  - ▶ mechanism of grammar constraints
- ASR is a practical implementation (?)

# Outline

- 1 Motivation: Why & how
- 2 Auditory physiology
- 3 Psychophysics: Detection & discrimination
- 4 Pitch perception
- 5 Speech perception
- 6 Auditory organization & Scene analysis**

# Auditory organization

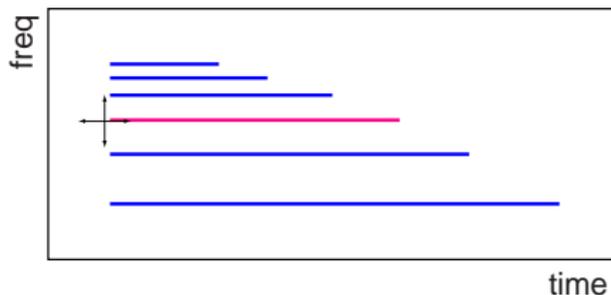

- Detection model is huge simplification
  - The real role of hearing is much more general:  
Recover useful information from the outside world
- Sound **organization** into events and sources

- Research questions:
  - ▶ what determines perception of sources?
  - ▶ how do humans separate mixtures?
  - ▶ how much can we tell about a source?

# Auditory scene analysis: simultaneous fusion

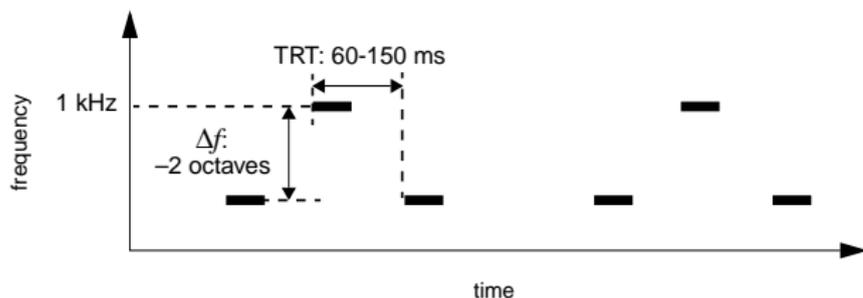

- Harmonics are distinct on AN, but perceived as one sound (“fused”)

- ▶ depends on **common onset**
- ▶ depends on **harmonicity** (common period)
- Methodologies:
  - ▶ ask subject how many ‘objects’
  - ▶ match attributes e.g. object pitch
  - ▶ manipulate high level e.g. vowel identity

# Sequential grouping: streaming

- Pattern / rhythm: property of a set of objects
  - ▶ subsequent to fusion ∴ employs fused events?

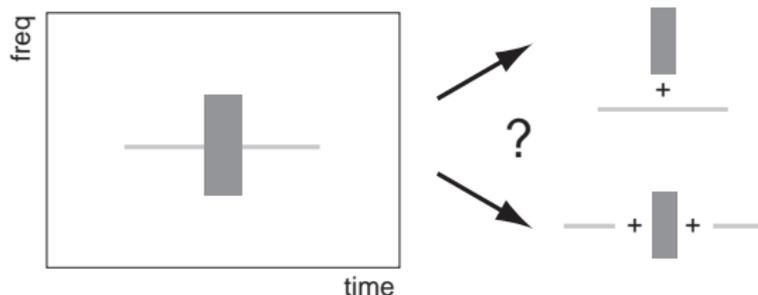

- Measure by relative timing judgments
  - ▶ cannot compare between streams
- Separate 'coherence' and 'fusion' boundaries
- Can interact and compete with fusion

# Continuity and restoration

- Tone is interrupted by noise burst: what happened?

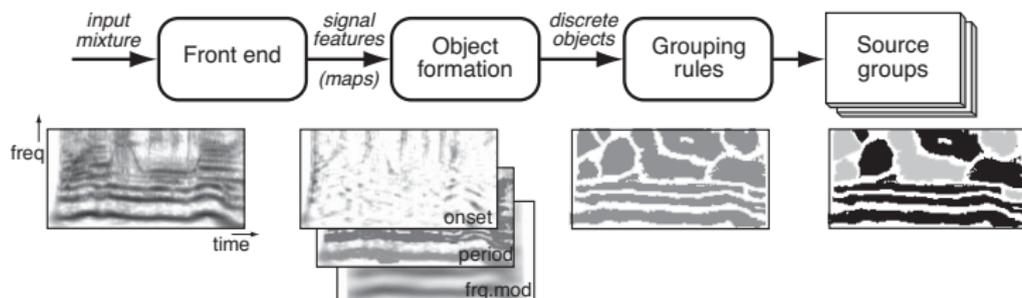

- ▶ masking makes tone undetectable during noise
- Need to infer most probable real-world events
  - ▶ observation equally likely for either explanation
  - ▶ **prior** on continuous tone much higher  $\Rightarrow$  choose
- Top-down influence on perceived events. . .

# Models of auditory organization

Psychological accounts suggest bottom-up

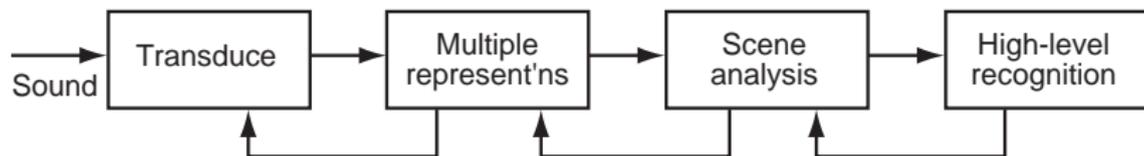

- Brown and Cooke (1994)

Complicated in practice

- formation of separate elements
- contradictory cues
- influence of top-down constraints (context, expectations, ...)

# Summary

- **Auditory perception** provides the 'ground truth' underlying audio processing
- **Physiology** specifies information available
- **Psychophysics** measure basic sensitivities
- Sounds sources require further **organization**
- Strong contextual effects in **speech** perception

## Parting thought

Is pitch central to communication? Why?
